Even though PSCs possess a rich tradition as the designated providers of individual counseling in the schools, the methods used for individual counseling should be evidence based, relying on research to establish the effectiveness of different approaches in the context of each presenting problem. In other words, while individual counseling is the intervention, evidence-based treatment (EBT) is the standard of care.

EBT is said to be taking place in a school's guidance office when the effectiveness of interventions can be justified according to research. Historically, PSCs were not enthusiastically involved in research. Cramer, Herr, Morris, and Frantz (1970) noted, "Too much effort is spent by counselors in evading the issue of validated knowledge, or in scoffing at research because the counselor is too incompetent to use the results" (p. viii).

More recently, Allen (1992) found that 84% of the PSCs in his study agreed that conducting research is valuable, and Bauman (2004) discovered that 69.5% of the PSCs in her study reported researching evidence of effectiveness before implementing a program. Finally, Cunningham and Henggeler (2001) pointed out, "If school-based services are to have a significant impact on targeted problems, logic dictates that evidence-based interventions hold the most promise" (p. 222).

Scope of Practice

Determining when to provide individual counseling requires a clear grasp of scope of practice issues. Otherwise, it would be impossible to justify spending several hours with one at-risk student while spending considerably less time with other students. Individual counseling in the schools is predicated on federal legislation, professional standards, ethical standards, state statutes, and case law. School policy, job description, principal's expectations, and school-specific characteristics give specific guidance (and protection) as well.

Scope of practice defined. Scope of practice refers to the boundaries establishing which duties fall to a specific group of licensed professionals and which fall outside their purview. Traditionally, licensed professionals acting outside of their mandated scope of practice face liability; hence, PSCs do not perform (among other things) hypnosis, appendectomies, or even assessments of intellectual functioning.

Much of the academic training for PSCs is geared also to mental health professionals seeking licensure as psychologists, clinical social workers, or professional counselors. Consequently, it is not surprising that some PSCs emerge from their academic training overwhelmed by the far-reaching breadth of a field that appears at times to promise healing of all school-age maladies. Scope of practice serves as a reminder of reasonable boundaries.

Federal Mandates

A good start to determining when and with whom individual counseling is appropriate is to examine federal laws establishing appropriations for school counselors to perform specific duties and to review PSCs' professional

and ethical standards. See chapter 46 of this text for a discussion of relevant federal laws and professional and ethical standards.

State Mandates

PSCs must be aware of the types of counseling they are specifically mandated by state law to provide, for such is the framework for grasping scope of practice of individual counseling. Many states refer to counseling that offers assistance with academic and career decisions and with social and personal problems. Posting your state's description of the PSC position serves to remind you and others daily of the state-mandated reasons for your presence in the schools.

State education laws and, to a lesser degree, state mental health laws, establish the PSC's scope of practice. From the section of the state code that establishes the school counselor position to the detailed school employee guidelines to the mental health professional dictates of confidentiality and a higher duty to report and to protect, state legislation is full of applicable references to the duties of PSCs. State code also offers scope of practice delineation among related professions that is significant to avoid overstepping of boundaries that draw the lines between PSCs and school administrators, teachers, and other mental health specialists, making the PSC's job more manageable, the caseload for individual counseling more reasonable, and the liability less tenuous.

When principals call on PSCs to administer corporal punishment or refill snack machines, a good grasp of scope of practice comes in handy. For example, one portion of the *Tennessee Education Laws Annotated's* outline of the duties of the school guidance counselor clearly establishes that they are "not responsible for general school administration or reports, except such as may be connected with the school's guidance program" (LexisNexis, 2003, p. 250). If your state doesn't have such a law to limit scope of practice, then legislative advocacy may be in order.

Likewise, when a student presents with significant mental health issues requiring long-term, intensive treatment, a firm grasp of scope of practice lead PSCs to refer the student to an appropriate mental health professional rather than attempting to operate outside of their training. Treating a student in need of professional mental health intervention is outside the PSC's scope of practice and as such opens the PSC up for liability as well as an unreasonable individual counseling caseload.

Look at the middle school basketball coach, for example. She may become concerned with one of her star player's golf swing or algebra difficulties or recent ankle sprain, yet realizing these fall out of her area of expertise, she would refer each of these problems to the applicable expert. Her job then becomes simply monitoring the progress by asking questions and being interested and concerned. Likewise, the PSC sometimes identifies serious problems getting in the way of school success. Realizing which of these problems to refer is as important as handling the problems that fall clearly within the scope of practice.

No profession can define a scope of practice (and give meaningful legislative input) without having a firm grasp of related professionals' scopes of practice. This is a challenging task, yet has the potential of reducing inappropriate demands and bad feelings in general. It is critical to know where our own boundaries end and another professional's take over, as it can become frustrating when another professional repeatedly does not understand your priorities, your limitations, your legal and ethical guidelines, or your scope of practice in general. It is your duty to communicate it professionally (citing sources) and repeatedly (if necessary), particularly when called upon to offer individual counseling that you have deemed inappropriate.

Besides the statutory mandates establishing scope of practice for PSCs, there are also significant statutory mandates establishing scope of practice for the professionals with whom the PSC most frequently comes in contact—teachers, principals, school psychologists, school social workers, school nurses, and the agencies that serve as in-school providers or outside referral sources, including mental health agencies, juvenile courts, and the state's children's services departments.

Teachers. Teachers are often the major source for identifying students who need individual counseling services because teachers spend so much time with students yet are unable to get off task long enough to offer specialized assistance. Mental health consultations, timely classroom intervention, classroom guidance instruction, feedback on standardized testing, and supportive listening are some of the ways to support teachers. Most of the teachers' legal mandates established by state law apply to PSCs as well, so there is a clear scope of practice overlap. Teachers need to be apprised on a need-to-know basis regarding students they refer to the guidance office, providing only the information obtained during individual counseling that is necessary to assist the student's success in that class.

Principals. The PSC shares many of the principal's foci regarding individual counseling, such as maintaining student record confidentiality, parents' rights, identifying at-risk students, enforcing zero-tolerance breaches, protecting civil rights, and adhering to all relevant state and federal laws. Therefore, communication with the principal regarding individual counseling with students is a necessary duty within the PSC's scope of practice. Such communication,

however, never discharges the PSC's professional obligations, such as duty to protect, as PSCs are professionals within their own right. Still, principals, as the administrative supervisors of PSCs, deserve to be kept abreast of all matters that fall under their purview, including but not limited to, notification when communicating with the following:

- School's attorney
- Department of children's services
- Police
- Courts
- High-risk students
- Anyone complaining about the guidance office services

Related professionals. Regarding school psychologists, school social workers, school nurses, and workers in mental health agencies, juvenile courts, and state children services departments, it would behoove the PSC to become as familiar as possible with the mandated roles of each of these in order to facilitate appropriate interactions.

Case Law

Case law (court decisions) constantly interprets scope of practice accountability. Criminal and civil cases at the state, regional, and federal level regarding PSCs specifically and education and mental health employees in general impact PSCs. Although many aspects of education law and mental health law fall outside of their purview, PSCs still benefit from studying court cases involving professional educators and mental health counseling professionals as well as those naming guidance counselors specifically.

Job Description, School Policy, School Characteristics, Principal's Expectations

Although it may seem self-evident, a clear understanding of and adherence to the duties described in the PSC's job description provide focus, decrease risk of liability, and justify the use of time. Likewise, school policy provides guidance and protection and should be carefully followed and regularly cited.

Hopefully, from the first interview as a prospective hire, the PSC has a firm grasp of the principal's expectations, from theoretical approach to school management to specific view of the priorities of a guidance office and where individual counseling falls in the organizational structure. School characteristics such as attrition, crime, pregnancy rate, and achievement scores likely impact the principal's emphasis (or de-emphasis) on individual counseling activities.

Facilitation of School Operations

Enhanced school functioning is the focus of all PSC's counseling services. Even if that is the clear aim, and it is determined that it cannot be accomplished in limited visits, a referral might prove more appropriate. The line between providing an open door and receptive manner and fostering dependence is one easily blurred, so the PSC needs to refocus students to the task of getting successfully through the school day when personal issues arise and empowering them to handle future problems with minimal intervention.

Since anarchy is the enemy of the school system, PSCs justify their individual counseling duties (and their very existence, for that matter) based also on their role in facilitating the smooth operation of the school. In their pursuit of efficiently running schools, principals and teachers often call on PSCs to act immediately to refocus students who have had their school day interrupted or who are interfering with the learning of others. The PSC who remains flexible can be a critical ally in the school's overall academic mission.

For example, a child may begin to cry in class due to grief issues or a teenager may become anxious and overly distracted due to an unplanned pregnancy scare. In both cases, the PSC must be able to accept a referral on short notice, complete an intake, and determine the necessary intervention to get the student refocused and back on task in the classroom. A short-term, solution-focused approach serves the needs of the school best. When a higher level intervention is needed, the PSC refers the student to the appropriate resource and targets the student as at risk, providing case management oversight.

Schools represent all of society's problems, and PSCs are called upon to intervene when children and adolescents behave as a manifestation of these problems. In order for teachers to focus on academics, PSCs intervene with students who are experiencing personal and social distractions from academic pursuits with the goal of restoring the student's academic present mindedness. The ethical standards of ASCA (1992) address personal needs of the student as the PSC's domain, making it appropriate for school personnel to rely on the PSC to intervene.

Safe Place

The guidance office should be viewed as a safe place for students who may have difficulty fitting in at times, such as those who are gay or lesbian, foreign born, homeless, of a minority culture, mentally ill, handicapped, or intellectually impaired, and even those who are intellectually or artistically gifted. Individual counseling with these students can offer acceptance and belonging.

After identifying the types of students for whom your student population seems an unlikely match, your efforts can ensure that they feel accepted and welcome in your office and in seeking your services. You cannot offer individual counseling if they never come into your office, so try to attract these students by making a point to target each identified population in ways such as the following:

- Acknowledge holidays and news events celebrating them.
- Highlight teachers and other school employees (as well as celebrities) with whom they identify.
- Provide information regarding laws and court decisions that dissuade prejudicial treatment of their population.
- Use and encourage embracing language which avoids heterosexism, sexism, eurocentricity, religiosity, and so forth.

Efforts such as these will not go unnoticed by the other school staff and should provide an opportunity for the guidance office to foster acceptance, embrace differences, and model the school official's role in supporting students.

Screening

Whether the students drop by just to talk or are referred due to behavior problems, use the opportunities to screen them. File student interests (both in your mind and in their file) such as "interested in debate" or "needs assistance with standardized test anxiety," so you can contact them personally when resources or opportunities arise. Try to remember that just because the squeaky wheel usually gets the grease does not mean the easygoing student should not rate your attention as well.

Every time you meet with a student, be mindful of ruling out the existence of any of the following:

- Danger of harm to self or others
- Duty to report or warn
- Zero-tolerance issues
- Medical problems
- Handicapping condition
- Need for an immediate response to facilitate school's functioning
- Good fit with any existing counseling groups
- Possible *Diagnostic and Statistical Manual* (*DSM-IV-TR;* American Psychiatric Association, 2000) diagnosis

DSM-IV-TR. School counselors must be aware of critical mental health problems common among children and adolescents, such as those listed in the *DSM-IV-TR,* just as they should be familiar with developmental milestones. Identifying and referring, rather than treating, becomes the focus when significant mental illness is suspected.

Regarding individual counseling, a good rule of thumb for referral versus in-school treatment is the inclusion of a preponderance of the students' presenting problems in the *DSM-IV-TR*. Problems that clearly fall short of a *DSM-IV-TR* diagnosis yet directly interfere with a student's ability to achieve academic goals during the school day are the purview of PSCs.

Just as some parts of society in general (Berk, 2003) and some early psychologists specifically (Buckley, 1989) treated children as little adults, "[h]istorically our understanding and classification of child psychopathology has been based on knowledge obtained from adult disorders" (Last, 1993, p. 29). The *DSM-IV-TR*, however, has a separate section devoted to disorders first evidenced in infancy, childhood, or adolescence, including

- Adjustment disorders;
- Attention deficit/hyperactivity disorder;
- Disruptive behavior disorders;
- Anxiety disorders;
- Mood and depressive disorders; and
- Substance and related disorders (American Psychiatric Association, 2003).

The *DSM-IV-TR* serves as a helpful tool during screening intakes to determine if the symptoms of a diagnosable mental problem are potentially present. If enough of the criteria is met to warrant concern, a referral to a licensed mental health professional to rule out or to confirm the diagnostic impression is in order. Although PSCs are not trained mental health diagnosticians, it is reasonable to expect they possess sufficient skills to make a diagnostic impression in the context of referring and assisting with educational plans.

Basic Competencies for Individual Counseling in the Schools

As stated earlier, PSCs should be competent to give help to those students who are in need of individual counseling. Egan (2004) offered as the operational definition of counseling, "An interpersonal relationship between someone actively seeking help and someone willing to give help who is capable of, or trained to help in a setting that permits help to be given and received" (p. 31).

Counseling is a skill and a process that is distinguished from advising, listening, and directing. It involves being tuned in to the student client both in thought and in feeling (Sciarra, 2004). While the student must assume some responsibility to participate fully, cooperatively, and willingly

in the counseling process, counselor competence is also an important factor, making positive outcomes possible.

So what makes a counselor competent to provide individual counseling in the schools? This is the question that many school counselor training programs seek to answer through their programs of study. Often, these training competencies are determined by outside credentialing bodies such as The National Council for Accreditation of Teacher Education or The Council for Accreditation of Counseling and Related Educational Programs. Accreditation by such entities is designed to protect the public against those who would masquerade as possessing certain skills and training. Credentialing provides, at the very least, minimally acceptable training and experience requirements and seeks to offer a common core of learning to all PSCs who graduate from accredited degree programs (Gibson & Mitchell, 2003; Sciarra, 2004). State licensure requirements may enhance competency further by requiring the demonstration of competency in additional, specialized areas.

The National Standards for School Counseling Programs and Suggested Student Competencies

Campbell and Dahir (1997) identified nine standards, three in each of the three areas: academic development, career development, and personal and social development. Attached to each standard is a list of competencies or desired learning outcomes of students served by school counseling programs. In order for school counselors to help students achieve these learning outcomes, they must be skilled in implementing interventions and programs that are designed to illicit results in these three areas of development. Keeping the national standards in mind when counseling students and competently implementing programs that address these areas helps maximize student learning and overall social and personal development.

Competencies in each of the following areas should be demonstrated when conducting individual counseling with students:

- multicultural issues;
- personal limitations;
- an understanding of how personal values and beliefs impact work with students, families, teachers, communities, and so forth;
- a repertoire of interventions and strategies that are developmentally appropriate;
- a familiarity with theories and theoretical techniques that are most effective with certain populations, issues, cultures, and so forth;
- access to appropriate referral sources;
- a knowledge of community resources, climates, and so forth that impact student performance; and
- discernment regarding legal and ethical issues, including case law that impacts school counselors' roles and functions.

While this list is not exhaustive, it gives PSCs an idea of the critical areas of professional development and training required to remain competent, skilled, and knowledgeable.

Appropriate Theoretical Orientations for Individual Counseling in the Schools

Once PSCs determine that a student is right for individual counseling, they must decide on which theoretical approach will best fit that student's unique set of circumstances. Theories provide guidelines that have been tested by experienced counselors and proven reliable through validated research. Theories help explain human behaviors and predict behavioral outcomes in certain circumstances. Theories also can help school counselors make sense of the human data they are given by students, parents, teachers, and administrators and then apply it in a coherent, meaningful framework that will assist the school counselor in developing strategies appropriate for each student's situation (Sciarra, 2004), such as their cultural identity. School counselors need to consider the larger contextual framework, plus the perspective of the student when choosing theoretical interventions. For example, failure to recognize, plan, and adapt to cultural considerations when working with students is unethical behavior and could harm the student.

Given the vast array of theories and theoretical techniques from which to choose, combined with the unique set of student circumstances, the PSC can be left feeling overwhelmed and unsure. This section will address those theories that have been proven most useful in dealing with student populations when conducting individual counseling.

Person-Centered Therapy

Developed by Carl Rogers, the person-centered theory stresses students' capability and responsibility to identify new and better ways to cope with their own lives. Students are experts on themselves and their lives, and they grow through self-exploration. Rogers (1951) emphasized the importance of the counselor who is warm, genuine, empathic, and caring. Counseling, according to Rogers, is a collaborative effort between the counselor and the client/student.

In order for the counselor to facilitate change in the client, three conditions must be present in the counselor:

1. Congruence/genuineness: Counselors are truly themselves when relating to students.
2. Unconditional positive regard: Counselors should have a deep and genuine caring for the student. According to Sciarra (2004), "in order to create an environment in which the child feels secure, school counselors cannot be judgmental, and they cannot personalize the child's successes or failures" (p. 23). Condemn the behavior, not the child.
3. Empathic understanding of the child's frame of reference: The school counselor must convey this understanding in a way that the child can feel. School counselors must see the child's world through their "glasses" while still retaining their own separateness.

Greenwood (2002) described the role of person-centered intervention with students who have survived trauma:

> Some children have such traumatic experiences that they need to defend vigorously against any thoughts or feelings which threaten to bring the painful memories back into consciousness. Repeated hurtful and traumatic experiences can affect the deeper structures of the brain, causing behaviour and learning difficulties, which are difficult to reverse. These defensive behaviours can be very hard for teachers to appreciate and cope with. Sometimes, when the threatened and feared feelings are triggered, a child's reaction can be beyond conscious control and reason, until they have calmed down. Very damaged children need emotional "holding," as well as a facilitating environment, to be able to learn and function acceptably in school. (p. 295)

Although the person-centered approach is an overriding philosophy in the schools (Colvin, 1999) and has been shown effective in several applications such as high school delinquency and crime prevention (Cassel, 2001) and self-acceptance promotion for children with disabilities (Williams & Lair, 1991), in its actual practice it is often superceded by time constraints and the immaturity of some at-risk students, resulting in a more directive, advice-giving approach (Colvin). While Roger's (1951) theory advocates for the counselor to assume a nondirective role that may prove to be ineffective in today's fast-paced world of academics, his underlying counselor characteristics are critically important, especially when building therapeutic relationships with children and adolescents in individual counseling and in other venues.

Reality Therapy

Developed by William Glasser (2000), reality therapy focuses on the here and now or the student's present behavior, and it does not emphasize the student's past. The past is only explored in order to understand the student's present behaviors. The goal of reality therapy is to help students take more effective control of their lives.

Glasser (2000) focused on the idea that all behavior is goal directed, that is, that people do not engage in behaviors from which they do not get something. All behavior is goal directed and designed to meet both psychological and physiological needs within the individual. It is the school counselor's role to determine what need(s) students are attempting to meet by the behaviors in which they engage and then to work with students in developing more appropriate coping plans for meeting those needs. This is often done through individual counseling with students. Through individual counseling, school counselors can explore, in more depth, the needs that drive student behavior and choice making. Students who learn to meet their needs in a positive and realistic manner develop a success identity (Glasser). Those students who meet their needs in irresponsible ways assume a failure identity. It is not the needs themselves that cause a student's problems, but rather the way he or she goes about meeting those needs. Reality therapy focuses on helping individuals develop personal responsibility for their own happiness and well-being.

Reality-therapy techniques have been shown effective with emotionally disturbed middle school students (Passaro, Moon, Wiest, & Wong, 2004). Also, Kyung-hee Kim (2002) incorporated reality therapy and choice therapy with play in developing the Responsibility Behavior Choice Program, increasing internal control and responsibility in Korean fifth graders.

When used in the school setting, and specifically within the context of individual counseling, reality therapy can provide the PSC with insight into what motivates student behavior. It can further help students see both short- and long-term consequences of their choices and behaviors, and help them learn to make better and more successful choices. The blending of reality therapy and choice therapy helps students understand that they can control their behavior and choose to behave appropriately (Grossman, 1990).

Adlerian Therapy/Individual Psychology

Much like reality therapy, Adlerian therapy views the total individual and sees all behavior as goal directed. Adlerian therapy has had a tremendous impact on today's school systems because of its utility of *social interest* or a sense of belonging to something outside of ourselves (Pryor &

Tollerud, 1999). Adler (1930, 1958) believed that developing social interest was most realized in the school setting and therefore, should be primarily addressed there.

According to Adler (1930, 1958) all behavior is purposeful and is designed to overcome perceived inferiorities and to develop self-actualization. Given a positive environment, human growth will take place. Much as in reality therapy, it is the counselor's role to determine what perceived inferiority is driving student behavior and interfering with a sense of belonging. Adler encouraged teachers and counselors to investigate the purpose of the negative behavior of students instead of simply reacting to that child's behaviors. An example of this principle in action follows.

A student was repeatedly sent to the counselor's office for attempting to "boss" his peers and his teacher. Whenever the teacher gave instructions to the class, the student would openly correct the teacher, reiterate the instructions, and point out peers who weren't following those instructions. His behaviors became frustrating for his teacher who felt he was attempting to usurp her authority in the classroom. Furthermore, his behaviors were isolating him from his peers because they saw him as a bully and a tattle-tale. The student, himself, was angry and frustrated at both his teacher and his peers, so the counselor decided to work with him in individual counseling twice a week for 30 minutes.

The counselor attempted to understand the purpose of the student's behaviors in the classroom by exploring how he felt before, during, and after his behaviors. She also explored his family situation, discovering that the student's family was homeless, often sleeping in several different places throughout the week, leaving the child feeling powerless and frustrated over his lack of control in his family life. The PSC then explored the student's feelings when he was bossing his teacher and peers, discovering that the student felt powerful and in control while acting out. The student was attempting to gain power and control in the only area of his life where he could: at school.

Once she discovered the purpose of the behavior, she was able to redirect his power seeking behavior to help him find ways to have healthy power, such as appointing him hall monitor at least once a week, allowing him an opportunity to exhibit healthy power. An immediate reduction in his bossing behaviors at school was observed, and rather than feeling isolated from his peers, he began to develop more of a sense of belonging.

Using the Adlerian approach in schools helps teachers, counselors, and administrators look beyond their emotional reactions to student misbehavior and deal more democratically with those behaviors. By seeking to understand the purpose of behavior rather than condemning/blaming the child, teachers and counselors maintain academic and therapeutic alliances with their students, increasing the overall likelihood of student success.

Although the Adlerian approach traditionally incorporates teachers and families when working with students who disrupt (Dinkmeyer, Pew, & Dinkmeyer, 1979), individual counseling has to suffice when families are unable or unwilling to participate (Sonstegard & Dreikurs, 1973).

Conflict resolution is one way, according to Clark (1994), to apply Adlerian principles to individual counseling in the schools. Focusing on cooperation, social equality, and mutual respect, the four steps in resolving conflicts, according to Clark, include

- Establish respect;
- Pinpoint the issue;
- Explore alternatives; and
- Share decision-making responsibility.

The Adlerian lifestyle construct is often a good fit with Latino Americans, as they interact individually within their Latin culture and with the majority culture (Frevert & Miranda, 1998). Therefore, counselors must gain competence in understanding and respecting the influences of their lifestyle, such as their history, cultural subgroups, effects of discrimination, family and social networks, possible language barriers, and the tendency to somaticize.

As with Latino Americans, Asian Americans tend to somaticize when feeling psychologically stressed, likely contributing to their reluctance to seek counseling and their preference for medical or spiritual intervention (Carlson & Carlson, 2000). In addition to reluctance to seek treatment, their reputation as a "model minority" due to their educational and economic successes (Sandhu, 1997) may be the reason Asian Americans are underrepresented in the cultural diversity literature. Still, J. M. Carlson and J. D. Carlson identified four specific aspects of the Adlerian model that are conducive to working with the Asian American population: "the focus on the client's social and cultural context, the emphasis on collaborative goal setting, the importance placed on the family environment, and social interest" (p. 214).

Watts (2003) summed up the appeal of an Adlerian approach to populations struggling to assimilate:

> Consistent with important multicultural emphases, Adlerian therapy is a *positive psychology* and approach to therapy that emphasizes prevention, optimism and hope, resilience and growth, competence, creativity and resourcefulness, social consciousness, and finding meaning and a sense of community in relationships. (p. 144)

Behavioral Theory

There are some situations where students, due to either developmental age, cognitive deficits, or other disorders,

are unable to grasp the abstract nature of some theoretical interventions. In these cases, often a straight behavioral approach can prove successful. Developed by B. F. Skinner (1953), behavioral theory views all behavior as a set of learned responses to events, experiences, or stimuli in a person's life. The behaviorist believes that behavior can be modified by providing appropriate learning conditions and experiences. By setting up specific experiences and conditions, the counselor can help students "relearn" more acceptable ways of behaving. The goal is for counselors to "recondition" students by focusing on specific behavioral goals, emphasizing precise and repeatable methods (James & Gilliand, 2003). Feelings are secondary to behaviors when using behavioral theory and the counselor takes on a more directive role. Behavioral counselors attempt to uncover the antecedents, circumstances, and consequences of human behavior, and to thereby probe into the ABCs of human behavior. Once these are uncovered, the school counselor can then develop interventions or behavioral plans that will recondition student behavior.

Many school counselors utilize this approach with younger or developmentally delayed students because it is simplistic and straightforward. The key to utilizing any type of behavioral therapy/plan is consistency in its implementation. School counselors must have the buy-in of teachers and others who interact with the student in order for behavioral plans to be effective across milieus.

School-based behavioral consultation and collaboration with mental health professionals is becoming more common (MacKenzie & Rogers, 1997; Reeder et al., 1997). Hussey and Guo (2003) measured behavior changes resulting when mental health professionals offered school-based behavioral intervention aimed at enhancing social competence and reducing negative emotions and behaviors in an urban elementary school with a population of severely disturbed students, made up predominately of African American males. They found decreased conduct disordered behavior, depressive symptomatology, and attention/deficit hyperactivity. Another study by Sapp and Farrell (1995) found a relationship between cognitive-behavioral therapy and academic achievement among African American middle school students. Additionally, cognitive-behavioral interventions stressing individualistic and self-deterministic qualities of feeling in control despite the environment are recommended for bicultural Hispanic Americans (Valdez, 2000).

Furthermore, prevention of antisocial behavior is potentially associated with positive behavioral intervention (McCurdy, Mannella, & Eldridge, 2003). Another study conducted by Miranda and Presentacion (2000) suggested cognitive-behavioral intervention, combined with anger management training is also efficacious in treating children with attention deficit hyperactivity disorder. Childhood anxiety disorders, when treated by cognitive–behavioral therapy, show long-term treatment gains, lasting 5 to 7 years (Barrett, Duffy, Dadds, & Rapee, 2001). Even preschool-aged children at risk for anxiety disorders can potentially benefit (Hirshfeld-Becker & Biederman, 2002). Cognitive–behavioral intervention may also be effective in dealing with childhood traumatic grief (Brown, Pearlman, & Goodman, 2004).

Solution-Oriented Therapy

Solution-oriented, or solution-focused, therapy was first established by Milton Erickson (1954). Due to the simplistic nature and unique approach of solution-oriented therapy (de Shazer, 1991), it has become a prime choice of school counselors when counseling students individually (Sciarra, 2004). The key to solution-oriented therapy lies in uncovering and utilizing exceptions to problem behaviors/issues in children.

When utilizing solution-oriented therapy, PSCs will first attempt to elicit from the students an example of a time when their problem was not present, that is, an exception. Once the exception has been identified, PSCs can then begin to look for the source of the exception. Was the teacher the source? The student? The environment? Under what conditions did the exception occur? By probing the exception instead of the problem, the counselor and the child are forced to look at preventative/corrective measures that they might have overlooked. Once it has been determined what source or sources are responsible for the exception, the PSC can then work with the student, teachers, parents, and administrators to expand the exception to other situations within which the child may be struggling.

As the counselor, students, and others work to expand the exception to other areas of the child's life, it is important to evaluate the process and to set goals for the student. Goals set for students should be specific, manageable, and meaningful to the student (de Shazer, 1991; Sciarra, 2004). They must also be measurable to the student and others who are invested in the student's progress.

The last step of solution-focused therapy is maintaining change over time. The idea here is to "teach the student to fish." One of the primary roles of a PSC, and any other counselor, is to empower clients to help themselves in the future. By helping students utilize the same process to solve other potential problems, PSCs are empowering their young charges to be self-actualized and to focus on solutions in their lives, rather than problems.

School counselors' use of interventions focusing on student outcomes has been shown to improve students' academic, social, and self-management behaviors (Webb,

Brigman, & Campbell, 2005). These interventions may also be in order during work with Asian Americans who often appreciate the prescriptive, brief approach the school day demands. Not only does the school environment often force the faster, more directive approach, but Asian American students themselves may press for a quick solution from the "expert" counselor (Corey, 1991).

Hope theory offers a goal-directed cognitive approach for PSCs. Research suggests students' level of hope plays a positive role in predicting well-being, academic success, and even athletic success (Snyder, Feldman, Shorey, & Rand, 2002). Another approach to solution-oriented therapy focuses on the stories adolescent students tell themselves and others. This involves the counselor's talking with students until stories emerge, and then facilitating the conversation until more useful stories develop. Biever and McKenzie (1995) accomplished this by

1. Maintaining a "not knowing" stance, by not being an expert about what is best for the student;
2. Being open to and helping to generate alternatives;
3. Thinking in terms of both/and, not either/or;
4. Assuming the student has both strengths and resources;
5. Being aware of own personal values and beliefs;
6. Working with the students, not their labels;
7. Including necessary others in the counseling process; and
8. Working toward understanding the students' situation and point of view.

Solution-oriented counseling in the schools can provide maximum benefit to students and counselors without lengthy, numerous individual counseling sessions, making it an excellent choice for today's overburdened school counselors.

Play Therapy

While play therapy will be discussed more in-depth in a future chapter, it bears mentioning here that PSCs need to play when conducting individual counseling with young children and even some adolescents. Young children (and those who have difficulty expressing themselves verbally) often will communicate through play. The Montessori school system was developed on the idea that play is the work of children (Sciarra, 2004). School counselors should be prepared to allow children the opportunity to draw, play, act out, and use drama and fantasy in their individual sessions with children. Often this is as simple as having a child color a picture and then tell the counselor about the picture. Play therapy can be as involved as having a child act out a family drama, or it can fall somewhere in the middle with the counselor and child shooting hoops in the gym while talking.

Fall (1999) found a connection between increased self-efficacy and a half-hour of play therapy each week for 6 weeks. Specifically, developmental play therapy is often utilized with prekindergarten children, aged 3 and 4, to help them with communication, interpersonal skills, self-esteem, and feelings of competency (Hoffman, 1991). Jungian play therapy may be effective in treating separation and enmeshment issues of elementary students (Allan & Brown, 1993). For the mentally deficient and the mentally retarded, even with accompanying emotional problems, play therapy may improve how they cope (Bernhardt & Mackler, 1975).

Individual cognitive–behavioral play therapy may be effective in treating encopresis (Knell & Moore, 1990) and other serious conditions. Adlerian play therapy is used for helping children build relationships, explore lifestyles, gain significance in school and in their families, and understand their behavior in the context of the school setting (Kottman & Johnson, 1993). Also, play therapy is recommended for disaster prevention and intervention in the elementary school (Yih-Jiun & Sink, 2002).

Hall, Kaduson, and Schaefer (2002) detailed 15 specific play therapy techniques to assist with understanding and expressing feelings, worries, and fears, and increasing self-control, impulse control, awareness of mind-body connections, self-esteem, problem-solving skills, relationship skills, and decreasing depression. One play therapy technique they suggested for students 4 to 8 years old is the use of puppets. It is less threatening to create a symbolic client (Kaduson & Schaefer, 1997) by allowing the child to talk through a puppet rather than directly about self.

Regardless of the age or presenting problems of the child, play therapy can provide the PSC with another avenue with which to explore meaning and discourse in the child's world. Utilizing play therapy can also help demystify the counseling experience for some children and make the school counselor's office a place to go for refuge and solace, as well as a place to discuss other, more serious issues. Despite these applications of play therapy, a survey of 381 elementary school counselors found that although most believed in its effectiveness, lack of specialized training and available time were barriers to its use (Ray, Armstrong, Warren, & Balkin, 2005).

While PSCs have their own theoretical orientations, they are often called upon to utilize a variety of techniques and interventions. Theories of counseling are the means to approaching a specific student with a specific problem because each student presents to counseling differently and must be treated as a unique individual.

XXVII
FOCUSED, BUT FLEXIBLE: A Developmental Approach to Small Group Work in Schools

JEAN SUNDE PETERSON AND HEATHER L. SERVATY-SEIB
Purdue University

Introduction

The Call to Be Proactive

In recent years, school counselors have been admonished to devote a significant portion of their time to proactive, prevention-oriented activities. Such curricula are intended to develop skills, attitudes, and knowledge that will support students throughout life (Campbell & Dahir, 1997). By intervening before problems begin or by addressing existing problems before they become crises, counselors can help students navigate complex developmental challenges, develop important interpersonal skills, gain support and skills for problem solving, and connect with peers in ways that contribute to being comfortable in the school environment. Prevention programs can be geared to optimizing wellness and school adaptation from the very beginning of the school years (Cowen, 1997).

Both large- and small-group work can be geared to prevention. Psycho-educational large-group work in the form of sequential classroom lessons or presentations to larger groups can target entire populations, such as age or grade groups (Kulic, Dagley, & Horne, 2001). Large-group work can serve as *primary prevention* (i.e., preventing academic, social, and emotional problems, offering support for meeting developmental challenges, and fostering resilience). Small-group work in schools also usually focuses on prevention, but is more likely to represent two levels of prevention work: (a) primary prevention and (b) secondary prevention (i.e., focusing proactively on populations targeted because of particular risk factors or problems). Small groups can also focus on *remediation* (i.e., working with populations already experiencing significant problems) for "a small but hardcore segment of the school population" (Baker & Gerler, 2004, pp. 4–7). According to Kulic et al., prevention should be recognized as a long-term goal, with effects of preventive group work often unclear until much later. They also distinguished prevention from intervention in regard to strategies and noted that "prevention efforts should not become interventive" (p. 214).

Overview

This chapter presents small-group work as a component of proactive, preventive school counseling programs. These groups are intended to help students learn and succeed in life. The main focus of our chapter is on the *practice* of group work, including what distinguishes group work in schools from group work in other venues, as well as how they are similar, the latter discussed in regard to theories. The practice-oriented research section emphasizes how practitioners can access pertinent literature, rather than summarizing empirical studies of outcomes. Finally, after discussing group work practices in general, we present a specific model for small-group work in schools: a focused, flexible, development-oriented approach, appropriate and potentially effective for both prevention and remediation.

Theory

How School Groups Are Similar to Other Groups

Therapeutic factors. Small-group work in schools is similar to group work in agencies, youth centers, and

treatment facilities in many ways. First, school groups can be as rich, complex, dynamic, and life altering as groups elsewhere, and Yalom's (1985) therapeutic factors apply to groups regardless of venue:

- interpersonal learning (learning about others' views of self and gaining skills related to interaction with others);
- self-understanding (learning about self);
- catharsis (experiencing and expressing, not holding in, negative and positive feelings);
- cohesiveness (having a sense of belonging);
- altruism (being helpful to others);
- universality (discovering common concerns, thoughts, feelings);
- installation of hope (seeing that others have solved problems similar to one's own);
- existential factors (facing issues related to life, death, pain, responsibility for actions);
- family reenactment (gaining understanding of self and family from family-like group);
- guidance (receiving advice, suggestions, information from group members); and
- identification (identifying with and imitating leader's and group members' behaviors).

Shechtman, Bar-El, and Hadar (1997) found that participants in psycho-educational and counseling groups for adolescents did not differ in attributing therapeutic factors to the group process. The language of comprehensive, developmental guidance (Gysbers & Henderson, 2001) includes learning about self and others as a key goal, and the Yalom (1985) factors of interpersonal learning, catharsis, self-understanding, family reenactment, universality, and identification are all related to that goal. Cohesiveness is related to the need to belong, commonly cited in literature as salient during the school years (Nelson, Rubin, & Fox, 2005; Risi, Gerhardstein, & Kistner, 2003). Installation of hope is certainly a desirable objective when working in the modes of secondary prevention and remediation. Existential factors apply to all modes of group work in schools, most notably in regard to children and adolescents coping with troubling life events and situations and accepting responsibility for behavior. Though it is possible that the last three therapeutic factors listed above would also be least noted by school-aged group members, they nevertheless apply here. School groups are not likely to focus much on family dynamics, per se, but insightful students capable of abstract thinking might indeed become aware of their own family's dynamics through interaction with others.

Well-trained facilitators avoid giving advice, but the factor of psycho-educational information might be part of a small-group curriculum in a school. Facilitators might judiciously provide information (e.g., about substances, disorders, careers, and development), and group members might offer suggestions for coping with problems. An intimate group setting provides opportunities for students to become well acquainted with each other, allowing for various positive behaviors that might not be visible elsewhere in school. Affirming and validating positive member and facilitator behaviors provides additional "information."

Group stages and dynamics. Second, group dynamics are likely to be similar. When school groups are closed and meet regularly over several weeks, they are likely to experience the stages of group development often noted in group counseling textbooks: Initial, Transition, Working, and Final (Corey & Corey, 2006) and Dependency and Inclusion, Counterdependency and Fight, Trust and Structure, and Work and Termination (Wheelan, 2005). When written and physical activities are frequently used, school-aged group members can challenge and resist the facilitator, group rules, and the curriculum in general. Unexpected movement into new levels of intimacy and investment can also occur, even when meetings are semistructured. Students and facilitators are both likely to notice when group dynamics shift. Facilitators cannot "make" a group cohesive, but by thoughtfully reflecting on group dynamics before and after meetings, they can develop strategies to enhance communication. For example, if a homogeneous group of high-control, verbally dominant high-achievers still seems to be collectively skittish about discussing social and emotional issues after five meetings, processing that perception is in order. If male and female eighth graders seem inhibited and distracted by each other, that perception can also be addressed, perhaps resulting in important forthright discussion about distractions, social development, gender identity and roles, and sexuality.

Norming. Third, the process of norming is as important and inevitable in school groups as it is in other venues, and it may occur through overt facilitator direction, or it may happen spontaneously over the first few sessions. We differ in our approaches to establishing guidelines in this regard, and therefore, we argue that the role of the facilitator in this process should vary according to style of facilitation, group composition, and size of group.

Termination. Fourth, school groups need as much careful attention to termination as do groups elsewhere. Regardless of age, members may have bonded with each other and the facilitator, and they may depend on the group for support and stability. Therefore, preparation for termination needs to occur in advance of the final session, and associated feelings need to be explored. Some sort of closing ritual, meant to affirm each group member and the group as a whole, is often the focus of the last meeting.

We typically advise our students not to change the basic format for the final group meeting (e.g., activity–discussion) because a changed format often significantly changes group dynamics. Some students might be uncomfortable in a more social context than previously, for instance, and no further meetings will provide opportunities to regain ease. Sometimes facilitators are also uncomfortable with the change, even though it is the group members who are the primary concern here.

Strengths-focus. Fifth, counselors of all varieties are trained to pay attention to client strengths. Effective school counselors, moving students toward self-awareness and successful coping, are alert for opportunities to stroke students' strengths credibly, with "accumulated evidence." In fact, group work is ideal for discovering and affirming strengths, including resilience, because facilitators can observe complex interpersonal processes, which provide rich information for generating feedback.

When group facilitators learn that struggling students have factors of resilience in their lives, they can note that these offer hope for breaking destructive and challenging cross-generational patterns. According to several noted figures in the resilience (e.g., Benard, 2004; Rak & Patterson, 1996; Werner, 1986) and hardiness literatures (Kobasa, 1979; Maddi, 2002), the following are factors that characterize individuals who thrive in spite of adverse conditions:

- problem-solving skills;
- ability to engage others;
- ability to be alert, spontaneous;
- desire for novel experiences;
- sustained primary caretaker early in life;
- role models outside of the home;
- various caretakers, a confidant;
- structure at home;
- proactive perspective;
- optimistic view of circumstances;
- positive vision of a meaningful life;
- self-understanding;
- not feeling responsible for family difficulties; and
- intelligence.

The first four might actually characterize students with attention-deficit problems, who may be quite successful as adults if they can find a good fit in employment and spouse/partner. These factors might also be found in students who simply know how to ask for help or build a relationship with a helpful adult. The next four may provide solid footing in the present. The next three represent potential movement. Proactive instincts help students to *do* something about difficulties. Being able to self-validate and look ahead, instead of becoming mired in the present, may propel young students forward positively. Self-knowledge, including understanding what is and is not one's responsibility, can help someone to stay above the fray. Last, intelligence is typically on lists of resilience factors and has been found to help generate options, among several benefits.

Facilitators can note strengths and factors of resilience even in students for whom school is uncomfortable (e.g., persistence in coming to school), in those who lack social skills (e.g., energy, ability to get attention), and in underachievers (e.g., courage not to do what everyone wants them to). Group members can also be encouraged to be alert to others' strengths and resilience and offer support and validation.

Specific theoretical approaches. Just as Yalom's (1985) therapeutic factors are applicable to group work in the schools, many other theoretical approaches to group counseling have been adapted for use in K–12 settings. More specifically, the scholarly literature includes formats/investigations associated with orientations such as Adlerian (Campbell, 2003; Clark, 1995), solution-focused (LaFountain, Garner, & Boldosser, 1995; LaFountain, Garner, & Eliason, 1996), reality therapy (Comiskey, 1993; Kim & Hwang, 1996), multimodal (Gerler, Drew, & Mohr, 1990; Stickel, 1990), cognitive-behavioral, and humanistic (Bauer, Sapp, & Johnson, 2000; Schechtman & Pastor, 2005). Adlerian and multimodal groups likely work well in school settings because they tend to be flexible, eclectic, and holistic and have an educational emphasis focused more on health than on sickness (Gladding, 2003; Lazarus, 2005; Mosak, 2005). The use of reality-therapy groups in schools is not surprising. This approach is straightforward, offers definable procedures for group facilitation, and stresses the importance of responsibility and accountability (Glasser, 1986; Wubbolding, 2001).

Many features of cognitive–behavioral groups make them a good fit for intervening with children and adolescents. They emphasize learning and the process of defining and evaluating specific goals, and they are focused on teaching specific skills, such as social skills (Gazda, Ginter, & Horne, 2001; Gladding, 2003). Humanistic approaches are attractive for group work with children and adolescents because they generally emphasize assets as well as deficits, unconditional positive regard, and the improvement of social skills (Raskin & Rogers, 2005). Also focused on strengths, solution-focused groups with children and adolescents allow for grouping children with diverse issues together and emphasize creating solutions rather than discussing problems (LaFountain et al., 1995, 1996).

Research

Although conducting literature reviews and building knowledge of research methodology and statistics may

not be central foci within most school counseling training programs, it is crucial that practicing school counselors remain abreast of the existing empirical and nonempirical literature and be knowledgeable and comfortable with the process of program evaluation. Familiarity with the steps involved in gathering and evaluating literature and applying basic research skills can help school counselors to plan groups, argue the need for and value of groups, and meet the challenges related to accountability. Rather than summarizing the data from outcome evaluations (see excellent reviews of the research in Riva & Haub, 2004; Claiborn, Kerr, & Strong, 1990), we offer practical tips for how school counselors can enhance their group work by using their research skills.

Planning for a group with a specific focus, whether related to presenting issue, member composition, or theory, can be facilitated by a review of the literature. Searches performed through databases such as PsycINFO and ERIC (often available in schools or in local community or university libraries) or through the Internet require the use of key words. These words are terms related to the purpose of the search. For example, for a group for children who have experienced divorce, a school counselor can examine previous empirical and nonempirical literature using key words such as *divorce*, *children*, *counseling*, and *group*. The database or Internet search engine then locates articles, chapters, books, or Web sites that contain these words. We recommend that these words be put in separately, adding an *and* between each key word while searching in PsycINFO and ERIC (including the word *and* between key words is not required for searching on the Internet). It is important to note that the search process frequently involves taking the attitude of a detective, since multiple attempts, using a variety of key words, usually produces the most appropriate references. For example, the word *counseling* could be replaced with *therapy*, the word *counseling* could be dropped to widen the search, or *school* could be added to include only citations specifically mentioning the school setting. Although school counselors may initially see them as tedious, these searches can result in valuable information that can be incorporated into their work with groups. Examples of the resources available include material on the effects of certain life events on the functioning of children/adolescents, suggestions for working in a group setting with specific populations, and various group formats previously developed and used by others.

A solid literature search of how children/adolescents are affected by specific life events can reveal important emphases and/or approaches that can be incorporated into the design of a group. For example, a review of literature on teenage mothers indicates that they have fewer interpersonal relationships than nonpregnant teens and less frequent and less positive interactions with peers and family members (Bogat, Caldwell, Guzman, Galasso, & Davidson, 1998; Passino et al., 1993). Outcome investigations also suggest that pregnant teens benefit from educational material on child development, parenting skills, and life-skills training (Griffin, 1998; Kiselica, Gorczynski, & Capps, 1998). Discovering and incorporating such information during the group-planning phase likely enhances the ultimate outcome of the intervention.

Issues that may be unique to certain populations often become relevant when facilitating groups, and the scholarly literature provides interesting insights into working in the schools with children/adolescents from various populations, for example, Korean American elementary school children (Smith, 1997), African American/Black high school students (Goldberg & Tidwell, 1990; Muller, 2000), and Native American youth (Appleton & Dykeman, 1996; Herring, 1996). In addition, Bilides (1990) offered guidelines for confronting issues of race, color, ethnicity, and class as they arise in the school-based group setting. Beyond issues of race/ethnicity, Muller and Hartman (1998) wrote about working in a group setting with sexual minority youth, and Peterson (1990) and Humes and Clark (1989) offered strategies for providing group counseling to gifted high school students.

The literature on counseling groups implemented in the schools contains a number of potential models and formats for groups focused on specific presenting issues. For example, models can be found for working in a group setting with children/adolescents who have experienced a variety of life events such as divorce (DeLucia-Waack & Gerrity, 2001; Pedro-Carroll, 1997), death loss (Finn, 2003), adoption (Kizner & Kizner, 1999), and parental military deployment (Mitchum, 1991). Formats can be found for school-based groups focused on students with diagnosed conditions such as ADHD (Webb & Myrick, 2003), mild handicaps (Hess, Rosenberg, & Levy, 1990), and learning disabilities (Flitton & Buckroyd, 2002). Innovative approaches to group work in schools have also been described. For example, group formats have been used to debrief middle school students after the sexual assault of a peer (Fenlon & Mufson, 1994), in rural settings to help parents guide high school students' career decision making (Jeffery, Hache, & Lehr, 1995), and in a collaboration between university and public school personnel, with graduate students providing group interpretations of career-related assessments to ninth-grade students (Usher et al., 1994). At a more macrolevel, group interventions have been integral to school-based physical and mental health clinics in urban settings (Chatterji, Caffray, Crowe, Freeman, & Jensen, 2004; Dryfoos, 1994).

PsycINFO and/or ERIC searches can illuminate empirical research that can help school counselors argue the value of group work to administers, teachers, and parents, including the effectiveness of various formats and

approaches. Both databases have a "limit search" option that allows for searching only empirical articles that contain the key words entered. School counselors should have at their disposal copies of meta-analyses done on school counseling outcomes (Prout & DeMartino, 1986; Prout & Prout, 1998) and group counseling outcomes for children and adolescents in a variety of settings (Hoag & Burlingame, 1997). These studies clearly show that group counseling is an effective intervention in schools.

Specifically, outcome studies support the use of school-based groups to improve social skills and interactions, as well as to enhance friendships (Salzman & D'Andrea, 2001; Schechtman, 1994; Schechtman & Bar-El, 1994; Schechtman, Vurembrand, & Hertz-Lazarowitz, 1994), raise academic performance (Brigman & Campbell, 2003; Slate & Jones, 2003; Webb, Brigman, & Campbell, 2005), decrease test anxiety (Wei, 2000), and reduce acting out and aggressive behaviors (Brantley, Brantley, & Baer-Barkley, 1996; Schechtman, 2001). Investigations of groups designed to address the difficulties faced by students at risk for poor outcomes and students who have experienced parental divorce found improvements in social, emotional, behavioral, and academic domains (Bauer et al., 2000; Hett & Rose, 1991; Kostoulas, Berkovitz, & Arima, 1991; Larkin & Thyer, 1999; Page & Chandler, 1994; Pedro-Carroll, Sutton, & Wyman, 1999; Sanders & Riester, 1996; Schechtman, 1993; Stolberg & Mahler, 1994; Zinck & Littrell, 2000).

Knowledge of the process of program evaluation can help school counselors to respond to recent and growing calls for accountability (Isaacs, 2003; Webb et al., 2005). Although empirical research on school-based group counseling does exist, more studies need to evaluate the effectiveness of such interventions (Riva & Haub, 2004; Whiston, 2002). Developing and implementing a plan for assessing the outcome of a group intervention can add depth and power to a group proposal, assist school counselors in more effectively and efficiently managing time, offer information on improving the delivery of the group, and provide valuable information to other colleagues within the field.

School counselors may find the prospect of engaging in research to be daunting, but it does not need to be an anxiety-provoking process (Corey & Corey, 2006). It is important to approach the process with an open mind. The ultimate goal of research does not need to be publication in an academic or other professional journal. Research can make a difference in the daily activities of school counselors and the students with whom they work—in program evaluation, for example. Program evaluation is a systematic approach to determining if a program "works"—that is, if a program has merit, value, and worth. Although a detailed description of the process is beyond the scope of this chapter, excellent and easily accessible resources are available for self-directed learning about program evaluation. For example, we recommend texts such as *Evaluation: A Systematic Approach* by Rossi, Freeman, and Lipsey, *Educational Evaluation:* by Popham, and *Utilization-Focused Evaluation* by Patton. A cost-effective place to begin is with online resources like those provided by the National Science Foundation, such as *The User-Friendly Handbook for Project Evaluation,* currently available at http://www.nsf.gov/pubs/2002/nsf02057/start.htm.

Practice

Explaining the Lack of Group Work

School counselors at all levels report that they value group work and that group work is possible at their schools (Dansby, 1996). Small-group work allows counselors to provide meaningful and high-impact services to several students at one time, including in several groups conducted concurrently. Therefore, counselors whose programs include substantial group work may not understand why others do not incorporate this efficient, effective delivery of services into their programs. After all, the American School Counselor Association (ASCA) advocates group work (Campbell & Dahir, 1997), and the Council for the Accreditation of Counseling and Related Education Programs (CACREP; 2001) requires preparation programs to train for it. However, regardless of how much can be accomplished by groups and regardless of research evidence about the effectiveness of group work in schools (Akos, Goodnough, & Milsom, 2004), group work may not be a significant part of school counseling programs. It is important to understand why groups may not be employed regularly or at all. Rare empirical studies of barriers to group work in schools have noted that nonguidance duties (Burnham & Jackson, 2000) and lack of time and access to students (Dansby) are obstacles; however, there may be other factors.

How Group Work in Schools Differs

Basic differences between group work in schools and group work in other venues may partially explain a frequent absence of group work in schools. In fact, awareness of these differences can help school counselors promote group work to school staff and other counselors—by highlighting what it is and what it is not. What follows here is a discussion of some significant differences.

Purpose. First, the purpose of school groups is usually different from the purpose of group work elsewhere. For instance, preventive group work occurs only rarely outside of the school setting, largely because hospitals and

agencies are not expected to focus on primary prevention (Kulic et al., 2001). School groups are seen as school-guidance curriculum, which both proactively and reactively supports academic, social, and emotional development. In addition, expectations regarding academic achievement often distinguish the school context. Implicit in the guidelines about development are the beliefs that counselors' work is fundamentally to help children learn and succeed in school and that learning is affected by personal, social, and emotional development. Understandably, given their pressures to raise test scores, teachers and administrators may perceive that the sole purpose of groups should be to help students achieve better academically. School counselors may also appropriately justify program components as ultimately "helping students learn." Group work focusing on social and emotional concerns might help students concentrate better, for example.

Second, school groups are generally not seen as part of a treatment plan. Though these groups potentially have an important therapeutic function, they are not intended to be therapy in the way that scholars and the public usually consider "therapy." For example, according to standard group work texts, group psychotherapy is focused on the remediation of difficulties in individuals with severe psychological disturbance (Corey & Corey, 2006; Gladding, 2003). Whether the purpose is prevention or intervention, school groups intentionally bring students together for focused discussion. Instead of being treatment-oriented, the groups are meant to enhance functioning in the school context.

Justification. School groups usually have a curriculum, which must be approved by administrators. It is difficult to justify taking time from academic work or other activities for group work if personnel perceive it to be only "hanging out" with the counselor. Group curriculum may indeed focus on particular behavior problems (e.g., anger management issues, Schechtman, 2001; poor social skills, Shechtman & Bar-El, 1994), life transitions (e.g., bereavement, Finn, 2003; parental divorce, Hett & Rose, 1991), or proactively on development (e.g., Peterson, 2007; Vernon, 1998a, 1998b, 1998c).

Session Structure. Because there should be defensible curriculum, some structure is warranted. A series of coordinated, sequential topics may guide discussion, for example; however, film clips, brief written activities, and kinesthetic activities can also provide structure and variety, help students to engage with each other, and move the group beyond superficial communication. Everyone is then likely to participate, even after being given permission to "pass." Shy, reticent, perfectionistic, or environmentally hypersensitive members may appreciate being able to share what they have written on a brief questionnaire. They have time to consider their thoughts, and sentence stems and other prompts provide expressive vocabulary, which then becomes familiar and accessible later. In addition, dramatic, crisis-prone members are less likely to dominate when all become used to the rhythm of taking turns sharing what they have written or created, at least during "go-arounds." Furthermore, inappropriate directions and disruptive behavior can be reined in by guiding the group back to the topic for the day. However, the structure referred to here is really semistructured, because discussion may move spontaneously in important, interesting, pertinent, and unexpected directions.

Having paper for "doodling" may help to diminish the emotional intensity associated with some topics for troubled students (Peterson, in press). Unsettling emotions are difficult for some children and adolescents to tolerate and express, and some structure and activities may help everyone be involved comfortably. Having quiet "toys" to manipulate may also help both young and older members to cope with emotions—for example, pipe cleaners, bendable sticks, or squeezable balls. If disrespect and disruption are issues, having speakers take turns holding a ball while the rest of the group listens might improve group behavior.

Recruitment. Recruitment is another challenge because group membership is typically voluntary, instead of being a required part of treatment. If group work is not familiar to a school population, recruitment may not be easy. Children and adolescents alike usually wonder who will be in the group being described to them. They may also be unconvinced that recess, being able to eat lunch with their friends, an interesting classroom activity, or time to prepare for an upcoming test is worth sacrificing for a group meeting, especially when they have no conception of what being in a group entails. Adventurous, social students might find the idea of a group appealing; others might view a first group experience as an uncomfortable unknown. Many facilitators prefer to screen students via individual meetings, not revealing names of other potential group members. The interviewer might say, "It's usually an advantage for a group to be organized without kids knowing who will be in it. Whether friends end up in the group or not, the experience will be a chance to know a *variety* of peers better."

The inherent social microcosm in each small group means that group work lends itself to important cross-cultural dialogue. Not only can communication among children and adolescents from various cultural and ethnic groups be facilitated, but discovery of developmental commonalities can also break down cultural barriers; however, organizers may have to be strategic during recruitment to accomplish this. Twice, we have seen how intentional

mixing of cultures and ethnicities in small groups can have positive outcomes. As a pilot project in one large middle school, school counselors invited approximately 60 students living in high-risk circumstances to participate in weekly, prevention-oriented groups for a semester. Intentionally, half of those invited were children of color. Of the 45 who returned signed parent-permission forms, half again were from minority groups. Each small group was culturally mixed, and the minority-culture students appeared to feel comfortable in group interaction. Until the final meeting, there was no mention of culture, per se; however, several indicated, when asked then, that they had indeed noticed the cultural mix and had appreciated the opportunity to become acquainted with each other. A follow-up, locally funded grant currently supports a larger group program called ON TRACK. Inviting almost all students of color in the participating middle schools (where they are approximately 20% of the school population), with less than half returning the permission forms, and inviting a much smaller percentage of the schools' Anglo students has resulted in evenly balanced mixed-culture groups and similar productive and barrier-breaking dialogue. We have concluded that students' being able to anticipate and experience cultural support in small groups is important. Once group work is successful, word spreads and recruitment becomes easier.

Marketing. In agencies and treatment centers, group work is likely to be unquestioned as an intervention; in schools, group work must *become* part of the school or guidance curriculum. In a sense, group work must be marketed—not just to students, but also to parents, whose permission is needed for students' participation; to teachers, whose cooperation will be essential; to administrators, who can help to generate support and who must provide space; and possibly also to the school board, who may need to be convinced that group work is an appropriate component of a school counseling program. These adult players in the school context, given current demands for accountability, may all perceive that affective development has little or no bearing on academic achievement and that group time could be better spent in the classroom or in tutoring. There may also be a collective uneasiness about group work, based on past experiences or misperceptions about group work. In regard to generating teacher support, one study found positive process evaluations when involving teachers collaboratively in referral and group-formation processes (Sullivan & Wright, 2002).

Some proactive marketing is therefore part of one course in the school counseling program at our university. Principals-in-training are required by their program to take Introduction to School Counseling. Their presence in the course generates important real-world dialogue, they gain perspective on appropriate roles for school counselors, and invariably they are awed by the complexity of school counseling and the rigor of the training. Among a multitude of course components, in order to create some understanding of counseling in general and school counseling in particular, this course includes an introduction to active listening through brief skill-building exercises, simulations of semistructured small-group work, and a demonstration of brief counseling.

The principals-in-training are typically skeptical about group work, including their concerns about parent complaints. Initially, they are noticeably uneasy during group activities, often joking that the class has now become "touchy-feely" and sometimes referring to well-known media figures who engage in confrontational problem solving. After a few instructor-facilitated demonstrations, they are required to engage the class in ten minutes of a semistructured small group activity, based on *Essential Guide* materials (Peterson, 2007). They gain an appreciation for the challenges of generating interaction, and they consider a wide variety of developmentally oriented topics in the process of choosing their focus. Ultimately, they recognize that small-group work is not what they had assumed, and that, even in brief experiences, some degree of depth in communication is possible. They quickly find commonalities, become better acquainted, and have some understanding of the possibilities and parameters of small-group work in schools.

Wise school counselors make no assumptions about receptivity among parents, administrators, teachers, or students to group work. Accordingly, counselors might devise a formal or informal marketing plan, potentially including newsletter items, informational letters sent home with students, and oral explanations at faculty meetings prior to and continuing after implementation. Through a newsletter, parents might be given a timeline, organizational structure (e.g., length of group series, number of groups facilitated concurrently, and an explanation of how missed classroom time will be accommodated), sample discussion topics, clarification of the "prevention" concept and the purpose of small groups, a description of the function of a facilitator, and a permission form. The last item may be included in a packet of forms at the outset of the school year for field trips and other activities where parent permission is needed. In addition, superintendents and school board ideally receive a rationale and explanatory material before an extensive group program is implemented, with the promise of an evaluation of the program after one year and perhaps again after a second or third year (since outcomes are not likely to be apparent quickly). Newsletters are useful for cultivating the soil for group work and can continue to provide updates regarding developmental foci.

To students, small groups can be advertised as "clubs," as the elementary-level exemplar in Littrell and Peterson's (2005) ethnographic study did, or as "discussion groups," as Peterson (1990) did at the high school level. The former believed that kids like the idea of being in a club. The stigma potentially associated with "counseling" argues for creativity and sensitivity in marketing small groups to students. Counselors in one large midwestern middle school, whose groups generally targeted children with identified risk factors, called all groups "concerns" groups, appropriate for the secondary prevention function of the groups. Choice of term should depend on whether the groups are intended to serve as primary or secondary prevention or remediation. As we will note later in this chapter, however, primary prevention language can be used regardless of purpose.

Facilitation. Group facilitation also differs in schools. Effective early-elementary groups should have an appropriate format, enough hands-on activities to engage members, activities that match their range of small-motor development, and a meeting length appropriate for short attention spans. In fact, developmental differences in school-age children across a wide continuum require that group structure, group size, screening, facilitator language, expectations about what constitutes "discussion," and meeting focus differ from age level to age level. Facilitation must be creative, skilled, flexible, poised, and tuned in to developmental levels. A discussion of several aspects of facilitation of school groups follows here.

The relationship. Because children and adolescents may understandably mistrust counselors, wise counselors take steps to build a comfortable relationship with them. An appropriate physical environment, clarity about what will be experienced, and language are all important (Thompson & Henderson, 2007). In addition, group facilitators should be comfortable with the populations they work with; genuine in communication; congruent in demeanor, language, and attitude; able to harness emotional reactivity; able to corral "teacher" instincts; and interested in working with groups of school-aged youth. The facilitator must be a person—with a personality, yes, but not someone who needs affirmation from the group, who self-discloses in self-serving ways, and who voyeuristically *needs* to know about the private lives and concerns of group members (Peterson, 2007).

Skills. Active listening skills are as important in group work as in individual counseling. When facilitators remember that the groups are about the group members, not about the facilitators, they are likely to employ appropriate reflection, validation of feelings, checking for accuracy, paraphrasing, and summarizing and to avoid self-disclosure, except, perhaps, in the form of immediacy (e.g., "I'm sensing some discomfort in the group. I'm seeing that in your faces."). Instead, they focus, with a one-down posture (i.e., group member as authority), on entering the world of the students, being taught by them, and facilitating interaction. They resist the urge to "fix" group members.

Facilitation of school groups typically does not employ hard-edged confrontation or intentionally create discomfort for therapeutic purposes. Group membership is voluntary. Any actions that appear to have the goal of discomfort are likely to turn away students with already tenuous commitment. Instead, the focus is another basic counseling tenet, an emphasis on personal strengths (Gelso & Fretz, 2001), helping students discover and affirm them in the interest of coping effectively with developmental and other challenges (e.g., "You'll use your intelligence to figure this out and get what you need." "You're a survivor." "It took courage to speak up for yourself.").

Nonjudgment. A nonjudgmental facilitator posture is crucial to building trust, particularly important when working with students who find it difficult to trust adults. All group members, regardless of age and circumstances, observe verbal and nonverbal nuances in facilitator responses. In groups in any venue, however, students who do not trust easily may immediately test the facilitator with rough language, comments meant to shock, and other disruptive actions. In fact, all or most members of a group might do this collectively, depending on group composition. Such behavior poses particular concerns in schools.

Rules. For defensible reasons, many group facilitators in schools set firm rules about behavior at the outset, adhering to school policy about language and behavior, thereby making a roller-coaster ride of "testing" less likely (but not impossible). Usually, some reference to basic courtesies is enough:

- respect for everyone and, therefore, no put-downs;
- eye contact, if that is comfortable, and respect for whoever is speaking;
- no talking when someone else is talking; and
- no talking about someone who is not present.

Asking young children to set rules for their group may certainly be appropriate; however, since many—if not most—school-aged group members have had no previous small-group experience, they sometimes appear to be uncomfortable when asked what rules should be set. They probably have no sense of what their "group" experience will be. Therefore, we recommend that the initial meeting involve an engaging, noninvasive, semistructured activity and discussion. At the end, the facilitator can say, "This is

what we're going to be doing in our group—talking and doing things together." Because membership is likely voluntary, a positive first experience is essential. If rules appear to be needed, they can be established at the second meeting. In fact, at the end of the first meeting, members might be asked to think about what rules would be helpful, to be discussed at the next meeting. Whatever guidelines are set, facilitators need to be consistent in encouraging and enforcing them, orchestrating with arms and hands if necessary (e.g., extending the arm in the direction of inappropriate behavior and saying, with palm facing away, "Hey—now wait a minute. Remember the rule about respect."). Such an action often suffices when needing to curb inappropriate behavior. Among several responsibilities, the facilitator is expected to lead and "manage."

Disruptive behavior. Some groups pose considerable challenges collectively. We argue that if facilitators can remain poised and nonreactive during disruptions, foul language, or disrespect of peers, while not allowing the behavior to escalate out of control, they are likely to gain the trust of the group. Then, language seems invariably to improve over time, as members relax and connect with each other in new ways, even though old language habits for expressing strong feelings may reappear now and then. It should be noted that, a week after a "breakthrough" discussion in which students leave bravado and façade behind, it is not unusual for a group with trust issues to slide back into testing the facilitator at the next meeting. Intimacy and expression of feelings may have been quite unsettling. Wise facilitators process the past week's session and present sessions, and then normalize the upheaval. It does indeed "make sense."

Modeling respect and poise. Facilitators also have the opportunity to model for group members. When they are unconditionally respectful of behaviors that might seem strange to others (e.g., a group member who cannot make eye contact and who may doodle microscopically throughout each meeting, one who cries easily, one with poor hygiene, one unconnected to peers in school), they model respect, affirmation, and nonjudgment. When facilitators do not challenge a "pass," saying instead, "I respect your choice" or "I'm glad you can set a boundary like that," they affirm a member's autonomy. When they do their job as a facilitator of discussion among student peers, without drawing attention to themselves with self-disclosure, they model objectivity and unconditional, focused attention, which can be amazing to students from emotionally enmeshed families. When facilitators reframe ineffective behaviors or revelations concerning "bad" behaviors, they model respect for and understanding of the function of behavior. When they stay poised in response to shocking disclosures, they demonstrate that *anything* can be discussed, no matter how painful and uncomfortable. When they respond to an inappropriate question about themselves, they can deflect it:

> It makes sense that you're curious, but the group is for you, not for me. My job is to help you communicate with each other as peers, and I'm not your peer, so I have to keep myself out. That's what I'm trained to do.

Access. Group facilitators in schools can have daily access to students between meetings, including being able to observe them in classrooms and lunchroom and to check in, informally. Such a vantage point may be especially important when bullying has been revealed or when symptoms of depression, suicidal ideation or attempts, an eating disorder, or substance use have been evident or hinted at in group meetings. For weeks and months after school or personal tragedies, facilitators can also monitor students beyond group meetings. In our experience, even students without personal connections to victims can continue to be highly troubled by deaths and other tragedies—sometimes because "the world went on" too quickly.

Logistics. Group work in schools is fraught with logistical challenges. These can be daunting to school counselors, who may decide that the payoff is not worth the energy required to make groups happen. Logistical concerns include finding space for meetings, not easy in buildings with 95% to 100% room utilization; scheduling meetings at times which interfere least with classes; developing a method for reminding students of meetings; and securing parent permission, since even supportive parents may forget to respond. When group work is embraced by parents and school personnel, logistical hurdles are easier to overcome, of course.

Space. Group privacy is essential, but not always easy to secure in schools. Any quiet room, preferably smaller than a classroom and with a door that closes, can suffice for group work. In the authors' experience, interns, required by standards of CACREP (2001) to conduct groups, have creatively used concession areas, media rooms, and corners of cafeterias for group meetings when conference or counseling rooms have not been available. Veteran counselors, wisely using needs assessments, evaluations, and formal and informal communication with teachers and administrators, can sometimes secure other areas as well for groups.

Scheduling. Scheduling group meetings can also be a challenge. Some principals discourage counselors from taking students out of classes such as physical education,

art, and music, since the teachers in those areas typically do not see the students every day and often have skills, performances, or projects for which regular attendance is critical. Other principals deny pullout for classes in the core curriculum. Still others recognize that meeting social and emotional needs is crucial to the success of the school and overtly support group work, including leaving any classroom. School counselors must, therefore, build credibility and market program components carefully, and they must be skilled in negotiation. They may be able to vary meeting times so that students do not miss the same class more than once during a 6-week period, for instance.

Certainly, school counselors must be sensitive to teachers, pressured as the latter are to increasing student achievement. Some teachers are likely to be unwilling to allow students to leave for groups under any circumstances. It might take a few years to build a relationship with those teachers sufficient to gain access to their students. Until then, groups scheduled during breakfast, lunch, or after school might be the only options for those students.

In terms of length and frequency, we believe that it is better to meet regularly—weekly—for even a relatively short series of meetings than to meet infrequently over a longer period of time. Teachers are likely to prefer a weekly rhythm, which helps them to know when to expect absences. Students then are also more likely to remember to come to group meetings; however, students usually need reminders, regardless of their ability, commitment, or school level. Basic to successful facilitation of school groups is determining the most efficient way to notify teachers and students. Especially for middle school and high school students, it is important to emphasize to both teachers and group members that missed work should be completed, students should remind their teachers before class that they will be leaving or will be absent, and they should get the assignment for the day.

Group Size and Composition. Group size needs to vary according to age and ability level, and this consideration makes school groups, certainly in elementary and middle schools, somewhat different from groups in other venues. A general guideline might be to match the number of members with age, conservatively, with perhaps 3 at grades two and three, 4 at grade four, and 6 to 7 in middle school (Peterson, 2007). The higher the verbal ability, level of social skills, and level of behavior, the larger groups can be. We do not recommend more than 8 or 9 at any level, however, even with gifted high school students. It is important that everyone be heard adequately at each meeting, including when structured activities require everyone in a circle to speak. A small group size means that members have an opportunity to become well acquainted beyond a superficial level. Small numbers, therefore, also contribute potentially to a sense of comfort and safety, less peer evaluation, and less perceived competitiveness.

With students at risk for poor outcomes, at any age or grade level, limiting group size is important because they especially need opportunities to be heard and to make significant social and emotional connections. Although it is possible that meetings can be as long as a class period, it is not unusual that school groups must fit into a 20- or 30-minute time period. In those situations, a small group size helps everyone to be heard.

Principals and teachers may request that the counselor "do something about" students with diagnosed ADHD, behavior problems, or suspected drug use. Counselors who are site supervisors often feel unable to address such needs because of time constraints. They may therefore recommend that an intern create a homogeneous group according to a particular behavior or disorder for their first group experience; however, a group of hyperactive students, for instance, is not conducive to focus. In general, we do not recommend that interns (or school counselors in general) facilitate groups made up entirely of students with significant behavior problems or with another kind of severe problem as the common denominator. Having group members who can model appropriate behavior and effective coping is important. In this regard, Kulic et al. (2001) recommended in-group heterogeneity, but "not so much that the group members have nothing in common on which to work" (p. 213). However, support groups for bereavement, divorce, or pregnancy are examples of groups justifiably homogeneous according to a common concern.

We believe that groups should be homogeneous according to age, when possible (Peterson, 2007). One or two years of age difference can mean a great deal of difference in social and emotional maturity. Even cognitively precocious gifted students may not be socially or emotionally advanced, even if they connect easily with adults. In this regard, grade-accelerated children may be mismatched with grade peers in an affectively oriented discussion group. Regardless of ability, it is more likely that 5 fourth graders will have similar concerns related to social and emotional development than 3 fourth graders and 2 sixth graders in a similar group. We hasten to add, however, that we prefer to group gifted children homogeneously by age and by ability because their sense of differentness means that they often do not trust that others can relate to their concerns. It may be difficult for them to be vulnerable and reveal limitations and concerns in mixed-ability groups. The literature suggests that though they experience the same developmental milestones as others, their developmental experiences are qualitatively different (Mendaglio, 2003).

Groups can help the genders—at any age—learn to comfortably communicate with each other. In that regard, it

has been recommended that genders be mixed in groups (Thompson & Henderson, 2007). We recognize, however, that boys and girls often communicate differently and may share more when the other gender is not present. Therefore, we often form same-gender groups when they are geared to primary prevention, especially prior to high school. When the goal is secondary prevention (e.g., coping with divorce or bereavement), we typically form mixed groups. We do recognize that there is controversy related to mixing genders in groups (Gazda, 1989).

Attendance. Attendance is another factor to consider in schools. A group comprised of seven students with poor school attendance may actually have only two or three attending on a given day. While the smaller number can be conducive to intimacy and depth of discussion, attendance patterns should be taken into consideration when ascertaining group size. In addition, though closed groups are preferable to open groups (Jacobs, Masson, & Harvill, 2002), erratic attendance can contribute to closed groups resembling open groups. Group dynamics then differ from meeting to meeting, with consequent loss of trust likely. In general, we recommend that group composition not change after the group is underway, no matter how much a new student might seem to fit a particular ongoing group.

Needs Assessment. In addition, some sort of needs assessment, formal or informal, should be conducted—not only to justify the groups to parents, teachers, and administrators, but also perhaps to market the groups to prospective members. Understaffed and with full, highly fragmented days, school counselors often find it difficult to step back far enough to assess needs formally, but such assessments can help to generate support for group work.

Confidentiality. Because more than one client is involved, confidentiality cannot be guaranteed in group work (American Counseling Association, 1995). In addition, regardless of how much facilitators emphasize it, several factors somewhat specific to schools may challenge a facilitator's ability to maintain it. Ethical standards related to parent rights, potential harm, and informing administrators are only general guidelines, and pertinent dilemmas are common.

In addition, significant differences in members' abilities and social and emotional development, even when homogeneous according to grade level, may mean that facilitators must take seriously the guidelines in pertinent ethical codes (American Counseling Association, 1995; ASCA, 1998) about protecting members—from each other and from themselves. The latter is especially important for school-aged children. In our experience, children and adolescents are usually discreet when choosing personal information to share. Nevertheless, we encourage counseling students to employ "orchestration" immediately when a group member says, soberly, "I'm going to tell you guys something I've never told anyone before." We advocate holding up a flat hand at arm's length, with fingers tipped up, and saying something like this:

> Hang on for just a minute. I want to say something to the rest of you. He is probably going to tell us something serious and important, and I want to remind you of our agreement about confidentiality. Are you trustworthy? He's respecting you here when he shares this. Now [looking at the talker], are you sure you want to share what you were going to say?

Facilitators should be *prepared for* indiscreet comments or dramatic revelations, including date rape, eating disorders, domestic violence, and substance abuse. In our experience, however, such disclosures are more likely to occur during one-on-one sessions outside of the group because facilitators are trusted.

"Jan," a first-year counselor in a middle school, experienced a complex ethical dilemma when her principal dramatically challenged her about confidentiality. She had established a group component in her program, facilitating several groups each week. Eventually, an eighth grader revealed to his group that he had committed minor vandalism to a teacher's home the previous year. A fellow group member told this to his parents, who were teachers in the system, and they in turn told the principal. No name was revealed. The principal, who did not support group work, pressured Jan to reveal the name of the vandal, saying that she would be fired if she did not comply with his request. After consulting with her former supervisor and considering pertinent ethical codes, principles of ethical decision making (Kitchener 1984), legal obligations, and the always tenuous trust factor in schools, she decided to hold her ground. She wrote a letter to her superintendent, focusing on ethical standards and her process of deciding, and fortunately, he supported her, although she decided before the end of the school year to accept a counseling position in another district.

Parents may also pressure group facilitators to reveal particulars—because they are afraid of what their children may disclose or because they are simply curious. It is important for facilitators to explain, perhaps in the permission letter, the parameters surrounding communication with parents, not unlike what might be explained about individual counseling. We also recommend, how-

ever, that group work be presented to parents as a "curriculum," which serves as a framework for discussion of development-related topics. Counselors should not expect laypersons to understand ethical guidelines, of course, and therefore, should be ready to articulate pertinent standards if asked.

Subgrouping. Subgrouping, which involves members splitting off into smaller groups in or outside of group meetings, is usually seen as potentially destructive to groups; however, contact among school group members is usually unavoidable between meetings, and it is possible that good friends find themselves in the same group. Friendships may also develop in the group, and in fact, that may be a goal of some groups. Nevertheless, group facilitators need to address, in meetings, any subgrouping that appears to be detrimental to group functioning.

Effect on Context. Effective small-group work, particularly when extensive and coupled with regular and coordinated large-group work, has the potential to improve the general school culture and climate over time. When bullying is pervasive, when teachers are hostile to each other and impatient with students, when "discipline" is usually punitive and harsh, when cultural and ethnic groups are at odds, and when parents believe that teachers are not sensitive to their children's needs, the very presence of group work in the system sends an important message: students have social and emotional concerns. That message, in turn, can generate sensitivity, compassion, and mutuality among school personnel. In addition, as students make connections and break through stereotypes, a ripple effect may occur — behavior and attendance improve, teachers relax and are able to focus on teaching, principals face fewer student attitude and behavior problems, and parents notice positive differences at home. More positive feelings about school, and about cross-cultural interactions, contribute to school pride and commitment to learning.

Peterson and Ray (2006) found that victims of bullying believed that their not being known by classmates made them vulnerable (e.g., when they were new to a school or when beginning middle school). Quality and quantity of friends are related to whether students are victimized (Hodges & Perry, 1999). Groups can serve an important school-climate function by helping students to make connections, be known, gain confidence, and find peers with common interests.

Littrell and Peterson's (2005) *Portrait and Model of a School Counselor* detailed a comprehensive program comprising almost exclusively small- and large-group work. Counselor Claudia Vangstad involved over half of the students in her school in her clubs simultaneously, while also regularly doing planned and ad hoc classroom lessons. Eventually, after her troubled K–5 school had been transformed into harmony and cooperation, she found that individual counseling was needed only rarely.

As another example, the first author, responsible for a special population, facilitated ten groups for gifted students per week for several years in a high school of 1500 students and perceived a significant, positive shift in teacher and administrator attitudes about social and emotional concerns of that population (Peterson, 1990). Arrogance became less of a problem in classrooms and elsewhere, and teachers regularly referred students to the groups when concerned about them. Group members found mind-mates, shy students had social contact, and group members greeted each other in the halls. At year's end, some students indicated that their group had helped them through difficult family or personal transitions. Some self-referred for individual counseling as a result of their group experiences.

Because group work in schools can be extensive, depending on investment and support, and because the student population is fairly stable over time, group work has the potential to effect significant change in an entire school. When groups help students find commonalities, lessen socioeconomic and cultural divisions, and become involved and comfortable at school, students can then turn at least some of their focus from social competition, bullying, and fighting to academics and school-based activities.

Development—Group Raison d'etre

The Common Concern. For primary and secondary prevention, there is often no one common concern that brings students together, unlike group work which is part of treatment (e.g., substance use, bereavement, anger management, eating disorders, problems with authority, criminal activity, or sexual molestation). In that sense, school groups are unlike community support groups or therapy groups in treatment centers. Developmental challenges can be viewed as the common denominator for school groups, regardless of whether groups are formed to address problematic behavior, career development, socialization, family transitions, peer relationships, or prevention of problems. Before we present our model for group work in schools, we will focus briefly on development, as related to school groups.

Developmental Goals. Counselors often work with people facing challenges related to life transitions, including normal developmental transitions (Corey & Corey, 1998). Indeed, a key tenet of school counseling, which is especially emphasized in comprehensive developmental guidance programs (Gysbers & Henderson, 2000), is that it is based on developmental principles and intentionally structured to support and enhance development, with curricu-

lum selected according to students' developmental levels. Indeed, school counselors are to attend to students' academic, career, and personal/social development (Campbell & Dahir, 1997). School counselors are resident developmental specialists in their schools, and ideally, their programs support development in *all* students, not just in those with obvious problems or those at risk for serious problems or those who are motivated and ready to learn. Group work is well suited to meeting broad developmental goals.

Formidable Challenges. All school-aged children are developing, of course, and they will continue to do so throughout their lifespan. All face, and will continue to face, general developmental tasks, with timing of task accomplishment varying along a wide continuum. For some students, these challenges are formidable. Traumatic life events, disabling conditions, family characteristics, environmental contexts, biochemical and neurological predispositions, and significant peers and adults all potentially affect developmental progress, no less so during the school years than earlier or later in life. Developmental "stuckness" can occur at any stage. School-aged children and adolescents, normally experiencing rapid change, however, are probably particularly affected by life circumstances largely beyond their control. It is important that educators, including school counselors, continue to learn about child and adolescent development and continue to use it as one template when assessing and providing educational and supportive services (Gazda et al., 2001).

A Template for Prevention and Remediation. A developmental emphasis in group work is appropriate for both types of prevention, regardless of where group members are on a continuum of development and regardless of their behavior or current emotional state. Facilitators can focus on pertinent developmental tasks (e.g., establishing a sense of competence, developing social skills, forging identity, finding career direction, differentiating from family, or developing mature relationships). This emphasis can help students of any age normalize developmental challenges, move over developmental hurdles, increase self-awareness, enhance sense of personal agency, anticipate developmental transitions (e.g., entering puberty, moving to a new school level, establishing romantic relationships, or leaving home after high school), and move confidently into the next stage of development. Students can share insights about cognitive, physical, social, and emotional development and can dissect the stress that often accompanies developmental challenges. Unfortunately, talking about development *as* development probably happens only rarely—even with peers. An actively listening, poised, developmentally savvy adult, with competence as a facilitator, may also be an unusual experience.

All students can benefit from small-group work. Those who appear to be functioning optimally, including gifted students (Peterson, 1990, 1998, 2000, 2002), might actually not be doing well behind a façade of confidence. They can benefit from group discussion on any number of developmental topics, feel heard, find support, connect to peers in a safe context, and feel more confident when facing future challenges. Students already having concerns in academic, social, and emotional areas can discover commonalities, feel heard and understood, and be supported by fellow group members during difficult times. Students who are in need of responsive services because of problems related to anger management, loss and grief, family illness, traumatic life events, problems with authority, or social alienation, for example, can benefit from straightforward discussion related to specific problems in support-type groups (Rainey, Hensley, & Crutchfield, 1997), but they can also benefit from interaction limited generally to developmental concerns (Peterson, 1990, 2007). The latter inevitably connects them to other group members, and that connection may be crucial to their moving forward positively. Similarly, students returning from treatment for addictions, eating disorders, or mental health crises may attend not only to issues related to their treatment, but also to related developmental challenges.

A Model for Small Group Work in Schools

The model we advocate for small group work in schools is versatile and defensible. Groups are supportive, facilitators are nonevaluative, and sessions are focused, but flexible. The group curriculum is intended to enhance functioning in the present and in the future, but not to "solve problems." When focusing on fostering students' social and emotional growth, facilitators are alert to personal strengths.

Versatile and Flexible, yet Focused. One distinguishing feature of the model we advocate for small-group work in schools is that it is appropriate for a wide variety of groups, regardless of whether there are presenting issues or risk factors. It is flexible in that facilitators are encouraged to be nimble, following strands that emerge in the interaction; however, there is also a clear, defined, defensible, and developmentally appropriate focus for each meeting. This approach can potentially enhance present and future functioning through increasing self-awareness and awareness of others and providing a rare opportunity to learn important, new communication skills. Achieving these objectives can lessen the severity of presenting issues and also help well-functioning students avoid problems. Fundamentally, developmental challenges, not presenting issues, are the focus of group discussions, even in groups geared to remediation. Regardless of group purpose, each topic is pre-

sented to group members as being important to "growing up." Each topic is presented as a "normal" challenge.

With this model, groups do not focus on symptoms of pathology or on "bad behavior," per se. Regardless of presence or absence of significant issues, and regardless of age, gender, culture, socioeconomic circumstances, comfort level in school or at home, or personal problems, we have found that children and adolescents appreciate an opportunity to focus on general developmental concerns in a small group with their peers and a stable, attentive, nonjudgmental adult. School-age children are more than their labels or problems, of course, and small-group work can function as crucial support during years of rapid and complex development. Furthermore, adults, including educators, do not know much about the inner world of youth. It is dangerous to assume anything about the internal experiences of students in schools—whether faces and behavior reflect distrust and animosity or competence and social ease.

Justifiable. As discussed earlier, any group curriculum must be justified to administrators. They need to be generally aware of what groups are discussing so that they can be prepared to respond to parents who suspect that group discussions air "family laundry" and teachers who wonder if groups criticize teachers or wonder if missed classroom time is justified. Facilitators, too, should be able to articulate the curriculum. Being able to say, "We've been dealing with stress for the past four weeks," "We're focusing on self-awareness and identity development this semester," or, more specifically, "We've been talking about bullying" helps to lessen anxiety and suspicion and also underscores that the groups deal with significant issues and are worth the effort required to surmount logistical challenges. Topics can be defended as developmentally appropriate and developmentally informative.

Generated by Assumptions. Several assumptions helped to generate our model and apply to groups regardless of age and developmental level:

- All students need to be heard and taken seriously.
- Shy students also want to be recognized and known.
- All students need support, no matter how strong and successful they seem and no matter how rough their exterior or how great their bravado.
- All students feel stressed at times.
- All students are sensitive to family tension.
- All students feel angry at times.
- All students feel socially inept and uncomfortable at times.
- All students worry about the future at times.
- All students, no matter how smooth and self-confident they may appear, need practice talking about social and emotional concerns.
- All students wear a façade at times.

Therefore, all students deserve and can benefit from development-focused discussion in small groups. Groups can provide a safe environment for addressing whatever students bring to meetings—stress, anger, social discomfort, anxiety, guilt, rebelliousness, and doubts, for instance. Group meetings can also help peers and facilitator "stand beside" members who are experiencing crises. In addition, students with problems related to classroom behavior, substance abuse, eating disorders, depression, obsessive-compulsive disorder, or conduct disorder, for instance, can make positive connections with peers and with a caring, nonjudgmental adult. Referrals to community resources are appropriate for severe disorders, given school counselors' time constraints and probable lack of specific expertise, but concurrent with receiving therapy elsewhere, students can participate in the group curriculum at school. The message to group members is that everyone is developing and facing basic, universal developmental challenges, even though circumstances make each individual's experience qualitatively unique.

Supportive, Nonevaluative. Ideally, small-group work in schools moves students momentarily out of a potentially competitive, evaluative environment into a context where no one dominates, no grades are given, and no one judges. The model presented here holds assiduously to the idea of nonjudgment, which is particularly important in the U.S. education system, which typically reflects the dominant culture value-orientation of individual, competitive, conspicuous achievement (Spindler & Spindler, 1990).

Unconditional affirmation may be absent elsewhere in students' lives—in homes with nonsupportive or inattentive parents, in homes where parents control with constant criticism and negativity, and even in situations where parents are highly invested in the school and social successes of their children. Potentially, all students appreciate a nonevaluative group facilitator who does not evaluate performance, and who can accept them without a "Yes, but . . . ."

Fundamentally, the groups we advocate put development at the center, rather than instructing, advising, or problem solving, which often characterize remedial groups. Development is the vehicle for establishing connections with others and fostering awareness and affirmation of self, regardless of whether group purpose is prevention or remediation. Members learn to adopt the nonjudgmental, developmentally oriented posture of the facilitators. Peers understand that it takes great energy to manage difficult situations. Academic work may not be a priority for

some students, and casual conversations elsewhere may be difficult because life does not *feel* casual. Regardless of school performance, group members support each other and explore coping strategies, while keeping the focus on development. Facilitators can affirm students where they are, not be preoccupied with where they ought to be.

Not Problem Solving. The model we present here also includes conscientiously maintaining a one-down posture, which puts group members into the "teacher" position. We have concluded that inviting students to talk about their own development-related experiences generates rich and edifying content; decreases alienation and loneliness; normalizes thoughts, feelings, and behaviors; and offers hope for success in the ongoing journey of development. Goals are not explicitly to eradicate problems or problematic behaviors or even to instruct, but instead to provide support for development. Developmental assistance potentially helps students to cope with difficult circumstances, assuage doubts and discomforts, and feel more connected to peers.

Personal and behavior problems might be resolved gradually as a result of the emphasis on development. Depending on etiology, such issues as underachievement, outbursts of temper, or substance abuse may gradually diminish. Study skills might be enhanced through having members talk about what strategies work and do not work for them, rather than approaching the topic didactically. Whole-classroom lessons are more appropriate for addressing study-skills training, but small groups can explore social, emotional, and environmental issues related to studying. Learning to study can be framed as a developmental challenge, one to be figured out. Obviously, if a problem is presented, or if a destructive group dynamic needs attention, the situation should be processed in the group. A brief, solution-focused approach (Littrell, 1998) can also be employed ad hoc, but specific problem solving is generally not the focus otherwise. A common stereotype of counselors is that they "solve problems." Therefore, providing students with an experience different from what was expected helps them to broaden their understanding of counseling and diminish negative stigma associated with it. They might readily seek it out in the future when needed—and before situations escalate into crises.

Developmental Objectives. The focus is on development—helping students understand it, normalize it, and manage it. Expectations are geared to the age and developmental level of the group. Developmental objectives such as the following, however, usually are appropriate for any age and level:

- increase self-awareness and affirm personal strengths
- gain understanding of developmental tasks
- gain insights about human nature
- gain skills related to expressing and articulating feelings
- develop social skills
- learn to give and receive feedback and compliments
- discover shared developmental concerns
- break down stereotypes
- develop trust
- develop effective coping strategies
- learn how to deal with stress, anger, fear, anxiety, and worry
- understand and find support for dealing with life transitions, including change/loss
- learn how to ask for and accept help when needed
- consider ways to relate with teachers and people in authority effectively
- learn how to deal effectively with "the system"
- develop skills related to self-advocacy

For all ages, probably most crucially for adolescents, the skills learned through small-group discussion will also help them in dating, marriage/partnership, employment, and parenting relationships. All of these areas represent ongoing development. New skills can help to break negative, nonnurturing patterns.

Focused. In general, the focus for group meetings is normally not a particular issue, behavior, need, or goal, even for remedial groups. Rather, the focus, not announced to members ahead of time, might be a concept or construct (e.g., multiple intelligences, success/failure, maturity, or depression), a theme (e.g., courage, transitions, personal strengths and limitations, loss, stress, coping, having fun, or making mistakes), a developmental task (e.g., forging an identity, developing relationships, or finding career direction), an issue (e.g., bullying, gossip, social exclusion, loneliness, expressing anger without hurting self and others, or unmet needs), a skill (e.g., giving and receiving compliments, or active listening), or an idea (e.g., that people allow tests and evaluations to "define" them, or that adolescents have more challenges now than in the past). A short series of meetings might be organized around one of these—stress, for example. Generally, we encourage facilitators to have some degree of closure on the topic at the end of each meeting—with reflection and summation. Closure gives facilitators an opportunity to commend group members for their seriousness, cooperation, and contribution. Even noting their progress in "becoming a group" is important affirmation.

Why have a topic to explore—an "umbrella idea"? Not all adolescents are as flexible as they might appear. On the other hand, some are quite flexible and, especially if

they are verbal and spontaneous, may prefer a loose format. They might say, "Just let us come in here and talk about whatever we want to." The flexible structure that we recommend is appropriate for a wide continuum of needs and personalities—from those who resist structure to those who are uncomfortable without it. By not announcing topics in advance of a meeting, facilitators avoid having students prematurely deem them "not interesting." If students ask, facilitators can say, "It will be a good one. Trust me." Facilitators probably should come to a meeting with two related topics in mind, however, in case one topic fails to generate discussion—perhaps because it was not developmentally salient.

Students who like order and structure and are uncomfortable without a "map" usually want group time to be worthwhile in specific terms. They might choose not to attend when something else seems preferable. They might also object to the fact that assertive or dramatic members set the pace and direction each time. They might conclude that the groups "don't really do anything." Discussion groups should not be just for students who talk easily—or for those who talk because they want to have control. In our experience, students appreciate the universality of developmentally oriented topics. They also are often surprised when they discover commonalities with peers in the group. Otherwise, socioeconomic status, culture/ethnicity, ability level, and course selection, for instance, may preclude communication with each other. Having structure, including a focus, "levels the playing field." Everyone is developing. No one can claim that growing up is not a challenge. Everyone needs skills—and practice.

Even with structure, group discussions need not be rigidly programmed. Direction can be changed nimbly. An altered group dynamic might need to be processed, or a school crisis or death of a peer might completely replace the planned topic for the day. A group member's potentially dangerous misinformation (e.g., about various drugs, sexually transmitted diseases, or depression) might prompt a facilitator to offer to bring pertinent information to the next session. In short, a good facilitator can accommodate various strands that emerge, yet gently steer the group to closure, overtly acknowledging that the focus inspired unexpected directions. Especially when topics appear to be intimidating and difficult, the focus is an excuse to persist with tough questions and deal with developmental challenges, not just gripes and frustrations. In that sense, the topic has an important function.

When facilitators are nonjudgmental and nonevaluative, maintain a one-down posture, and keep the focus on development, students who may be secretly distressed are likely to seek them out for consultation. Facilitators who have earned the trust of their groups can provide a critical and potentially life-saving function by generating a request for help.

Avoiding Jargon. We believe that focusing on self-esteem, motivation, or friendship, per se, is generally not productive. That is not to say that enhancing these is not a worthy goal. Rather, by facilitating meaningful and pertinent discussion about developmental challenges, helping students make solid connections with each other, enhancing social skills through activities and discussion, and generating rich information about development, groups potentially enhance how members feel about and view themselves and how much they care about schoolwork. Whether they are all pregnant teens, unwed fathers, substance abusers, underachievers, extreme introverts, or high achievers, or whether they fit more than one of these categories, focused, flexible, topic-organized discussion can indeed help all to survive and find support, enhance well being, and feel better about present and future. Self-esteem and motivation are probably both related to developmental challenges, and friendship skills can be enhanced through making connections about development. Therefore, focusing on developmental topics makes sense.

Sample Sessions

Primary prevention. An example of a primary prevention session format and focus, using a paper-and-pencil activity, is entitled "Family Roles" (Peterson, 2007) and can be used at late-elementary through high school grade levels. In this session, students check which of approximately 30 family roles (e.g., peacemaker, gets the most attention, gets the least attention, easy to raise, easily upset, sensitive, responsible, hot-tempered, or leader) are theirs at home. After they read their list of roles, other members can ask for elaboration on various roles. The facilitator keeps track of the roles mentioned, and the group guesses, at the end, which roles were listed most often. Members then mark roles they enjoy or are uncomfortable with and articulate associated feelings. The facilitator introduces the idea that a family member may do a role so well that no one else has to do it. Discussion follows. Students speculate about whether they think they will assume similar roles at work or at home in the future. This session's focus is on development as related to relationships—in this case, with siblings, parents, and family.

Secondary prevention, focusing on teens beginning to be involved in cross-cultural harassment. This session, without a hands-on activity, is entitled "Does the Stereotype Fit?" (Peterson, 2007) and is related to identity development. The group may purposely include students from two or more cultural groups. After being asked to define *stereotype*, students share how they themselves might be

stereotyped in school. Then the facilitator asks how they do and/or do not fit the stereotypes mentioned. The discussion then shifts to what members wish classmates, teachers, and parents understood about them.

Even early adolescents and late-elementary children generally engage readily around this topic. The word *stereotype* might be new to them, but they certainly know about critical judgment of and by peers who do not know them. Usually, having group members first speak about how they think others view them, instead of vice versa, safely opens up the dialogue to direct references to positive and negative assumptions. The dialogue isn't *about* people from another culture; it is *with* them. As after any discussion, it is important to process it: "What was it like to talk about stereotypes with a group that has kids from many cultures in it?" It is not unusual to hear comments that begin with "I never thought about that before . . ." or "I think it's not very nice to look at someone you don't know and judge them" or "We are a lot alike" or "I think it's nice how they care about their cousins and relatives so much."

Remediation, focusing on students expelled for fighting. A session entitled "In Control, out of Control," again involving just discussion, encourages students to reflect on the idea of control. The facilitator invites them first to describe situations and locations where they feel in control (e.g., manipulating, intimidating, having a temper outburst, being with a best friend, or working at a job) and then what they associate with feeling "out of control" (e.g., intense emotions, violence, social situations, drug use, fears and anxiety, developmental transitions, walking in crowded school hallways, or sexual feelings). Discussion then focuses on the extent members feel in control, their feelings about people who seem to be in control, normalizing out-of-control feelings, and how adults in their lives reflect "control." Though the facilitator maintains a nondidactic, non-problem-solving posture, discussion may move toward strategies for achieving a sense of control. This strand can be framed (and summarized to members later) as related to social, emotional, career, and academic development; skill-building; and support for moving to the next stage of "growing up."

Enhancing Lives in the Present and in the Future. Not only can school groups enhance mental health and help students survive difficult situations, but they also might help to decrease domestic and community violence in the future. Improved communication skills and the discovery that others are also struggling with developmental concerns are likely to help future partner and parent–child communication, not to mention work relationships. Behavior in those contexts will likely be affected by the interpersonal skills, attitudes toward others, and self-concepts that develop during the school years.

Groups provide both well-functioning and poorly functioning students an opportunity to develop skills related to expressing "emotional language." For example, they can learn that fear, worry, anxiety, frustration, irritation, sadness, disappointment, and anger can be talked about with others, as can joy, satisfaction, delight, and intense interest. Adolescent difficulties related to identity are normalized when group members share their confusion and concerns. Discovering that peers share many of their concerns helps adolescents to feel less lonely, less awkward, and less concerned about a critical "imaginary audience" (Elkind, 1984). If students feel connected to others, they are less likely to feel disenfranchised, perhaps resulting in less aggressive behavior and externalizing difficulties (Hymel, Rubin, Rowden, & LeMare, 1990), improved classroom adjustment (Mannarino, Christy, Durlak, & Magnussen, 1982), and even decreased criminal activity in the community (Schaeffer, Petras, Ialongo, Poduska, & Kellam, 2003).

Discussion can also explore real and potential relationships—with siblings, teachers, peers, persons in authority, and romantic interests. Perfectionism, substance abuse, eating disorders, depression, and sexual orientation are potential foci as well. Groups can also talk about "the system" and consider ways to self-advocate effectively in it. They can learn how to ask for help when needed and can be encouraged to be appropriately "selfish" in terms becoming educated—for present and future benefit. They can also learn how to give and receive compliments and other kinds of feedback.

Future Directions

Recommendations for Preparation and Practice

Because group work is integral to a well-planned, well-articulated school counseling curriculum, counselor educators need to maximize the impact of the typical group-training course on future school counselors by integrating content related to group work in schools and also by attending to group principles elsewhere in the preparatory curriculum, especially during field experiences (Akos et al., 2004). In terms of later professional development, workshops need to address real needs of school counselors in regard to group work. Wiggins and Carroll's (1993) subjects, for instance, had many concerns related to group leadership, group process, organizational issues, techniques, rules, and goals. Systematic national advocacy of small-group work in schools, with easily accessed workshops for training and

retraining, can help veterans and novices alike to incorporate small groups regularly into their programs.

Recommendations for Research

Process and outcome research have been neglected. Kulic et al. (2001) examined a large body of research literature related to prevention-oriented group work for youth and made recommendations for ensuring quality and replicability: (a) careful documentation (e.g., member characteristics, prevention goals, techniques, theoretical orientation, duration); (b) true experiments; (c) follow-up assessments, including parents and teachers; and (d) facilitator training, especially for unstructured group processes. Experimental process and outcome studies comparing groups employing the practice-based model presented here with control groups would illuminate the impact of a strictly developmental focus. Follow-up studies could examine developmental gains and hardiness, with implications for "teaching resilience."

In addition, more studies of the long-term effects of large-scale, systemic group programs on school climate, school metrics, family, and community are needed. Cross-cultural groups, in contrast to culturally homogeneous groups (Bilides, 1990), offer opportunities for examination of the effects of developmentally focused group work on cross-cultural communication, school violence, attendance, and academic achievement, for example.

Conclusion

A small-group component in school counseling programs allows counselors to provide an important, multifaceted service to many students concurrently. Groups can be directed toward primary or secondary prevention or remediation. Regardless of purpose, however, development is at the heart of group work in schools, with the focus on helping students successfully meet developmental challenges. School groups are usually similar to groups elsewhere in terms of therapeutic factors, group dynamics, norming, termination, and strength-focus. However, group work in schools often differs significantly from group work elsewhere in regard to purpose, content, structure, recruitment, marketing, facilitation, logistics, group size and composition, attendance, needs assessment, confidentiality, subgrouping, and effect on context, as well as the reality that development is the common concern and can be addressed, per se. Several of these differences might explain the lack of group components in many school counseling programs. The model for group work presented here incorporates all of these similarities and differences, but sustains focus on development regardless of presenting issues and regardless of group purpose.

XXVIII
CONDUCTING GROUPS IN SCHOOLS: Challenges and Rewards

DENISE BEESLEY AND LISA L. FREY
University of Oklahoma

Introduction

Groups are integral to human development. We enter the world as part of a family group; we work, learn, and often play in groups. For these reasons, in schools, group counseling is a crucial component of every comprehensive developmental guidance program. Fortunately, the school setting actively lends itself to the constructive use of group counseling as a vehicle for addressing the respective developmental needs of elementary, middle school/junior high, and secondary students. In addition, group counseling has other important advantages, including the following: (a) It is a time- and cost-effective modality for helping students achieve academic, personal/social, and career success, consistent with the National Standards for School Counseling Programs; (b) it allows counselors to serve larger numbers of students with a greater variety of problems; (c) it provides real world experiences, including a sense of belonging, connection with others, and opportunities to learn from others; and (d) it allows students to help each other with problem solving, modeling, and practicing skills (Baker & Gerler, 2004; Campbell & Dahir, 1997; Davis, 2005; Gladding, 2003; Schmidt, 1999; Sciarra, 2004; Studer, 2005). Groups are also recognized as the preferred mode for delivering a range of counseling and psychoeducational services in educational settings by the American School Counselor Association (ASCA; 2003).

In this chapter, we present an overview of the unique issues involved in conducting groups in schools. These include definitions of terms and purposes and discussion of challenges and considerations; extant theories, research, and practice; accountability; and future trends and innovative practices. We also examine the contributions and limitations of various theories and the impact of contextual variables on the academic, social, and emotional functioning of children and adolescents in school settings. In the discussion of future trends and innovative practices, we propose consideration of the relational–cultural theory (Jordan, Kaplan, Miller, Stiver, & Surrey, 1991; Miller, 1984) as a vehicle for maximizing the potential of group work in promoting social and emotional competence among students, counselors, teachers, parents, and administrators. In order to infuse the material presented with a more practical, user-friendly format, we intersperse facets of a group counseling scenario throughout various sections. We hope that the mix of pertinent background information interwoven with aspects of a group in action will be a useful resource for school counselors and will encourage and support them in their continued good work with students.

Definitions, Purpose, and Rationale

Schmidt (1999) defined group counseling as "a confidential helping relationship in which the counselor encourages members to focus on developmental, preventive, or remedial issues with which they are concerned" (p. 161). The purpose of group counseling, according to Schmidt, is "for members to explore issues affecting their development and to form intimate relationships in which they accept and support one another in the process of resolving and coping with their concerns" (p. 163). Obviously, group work in schools may be conducted using small groups or larger group classroom guidance formats. While the two are similar in some respects, they do differ in several key areas including size, purpose, scope, functioning, interaction processes, and group dynamics. For example, guidance lessons are generally preventative and psycho-educational in nature and are conducted with all students in a particular grade within the confines of the classroom. Small groups,

on the other hand, focus more on counseling-related issues such as personal growth and interpersonal relationships. For the purposes of this chapter, we focus on small group counseling work in schools.

Children and adolescents come to school with an array of needs and problems. With the realities of war, school and community violence, and domestic abuse graphically displayed in the media and, sometimes, in students' daily lives, it is no wonder that students are often apprehensive and anxious about their feelings, experiences, and relationships. Because groups mirror real-world relationships and schools, in many respects, are microcosms of the larger society, educational settings provide an ideal environment for individuals to safely explore relationships and personal beliefs, values, and feelings. For example, group processes foster the development of deeper intrapersonal and interpersonal insight, empathy, perspective-taking skills, and social and emotional competencies that are imperative for building and nurturing healthy relationships with others. They allow members the opportunity for self-examination, to learn and practice new coping and relationship skills, to problem solve, and to share their experiences in a caring, supportive environment (Davis, 2005; Schmidt, 1999; Sciarra, 2004).

Historical Perspectives on Group Work

The history of group counseling in America can be traced back to hospitals and schools at the beginning of the 20th century. The first psychotherapeutic group was conducted in 1905 in a Boston hospital setting with tuberculosis patients. At about this same time, classroom guidance work was being implemented by such pioneers as Eli Weaver, Jesse B. Davis, and Frank Parsons. Their seminal work in guidance and counseling continues to proliferate in schools across the nation today. Group work continued to evolve during and after the mental health movement of the 1920s. During this period, group counseling was prominent in child guidance centers using a model developed by Alfred Adler. Group counseling entered a new phase after World War II, when large numbers of returning veterans and a shortage of therapists led Dr. Carl Rogers and several of his colleagues to develop a model based on his Person-Centered Counseling Theory to train counselors to work with individuals in a group format. This eventually led other theorists such as Albert Ellis (Rational Emotive Behavior Therapy), William Glasser (Reality Therapy), and Fritz Perls (Gestalt Therapy) to adapt their techniques to group work as well. Shortly thereafter, these theories, among others, were adapted for use with groups in school settings. Other types of group modalities emerged during the 1960s and the 1970s; some are more accepted than others.

As a result of ethical concerns related to certain types of group practices during this period, the Association for Specialists in Group Work (ASGW) was established in 1973. This professional organization went to work quickly to establish practice guidelines and standards for the field and promote research and best practices in order to better regulate the specialty profession of group work. Since then, other counseling organizations have added divisions to represent counselors who do group work (e.g., American Psychological Association [APA], Division 49, Group Psychology and Group Psychotherapy). Today, group work is conducted in a variety of settings, including schools, universities, hospitals, community mental health clinics, private practice offices, businesses, and so forth.

Theories of Group Counseling in Schools

Developmental Theory

As mentioned previously, several theories for counseling individuals have been modified for work with small groups. However, because any counseling intervention in an educational setting must be appropriately adapted to students' current levels of functioning, developmental theories are used to undergird other counseling interventions. Utilizing developmental theory in working with children and adolescents is especially important in view of its emphasis on physiological, psychological, and social processes from birth as well as the interactions among individuals and their environments. The developmental needs and processes of children and adolescents have been explored and examined in the works of Gesell and Ilg (1946), Gesell and Ames (1956), Havighurst (1953), Kagan (1962), Bloom (1964), Erikson (1963), Piaget (1970), Kohlberg (1969), Gilligan (1982), and Super (1990), to name a few. Developmental theories, especially those that consider the impact of contextual issues on student functioning and identity development (e.g., Gilligan), are an excellent fit for group work in schools because they provide a structure for gauging development in children and adolescents and for developing age-appropriate activities and competencies to promote optimal skill development for all students.

Counseling Theories

In conjunction with these developmental perspectives, a variety of counseling theories have been developed and utilized in school settings to conceptualize and illuminate individual and group functioning. Some of the most frequently applied models include (a) Person-Centered Therapy (Rogers, 1951), with its emphasis on the therapeutic condi-

tions of genuineness, empathy, and unconditional positive regard to promote interpersonal awareness, insight, and positive change; (b) Rational Emotive Behavior Therapy (REBT; Ellis, 1962), which focuses on challenging irrational thinking; (c) Reality Therapy (RT; Glasser, 1965), which emphasizes the development of the "identity" and taking responsibility for one's behavior; (d) Adlerian Therapy (Adler, 1998), with its emphasis on examining the purpose and goals of behavior to gain insight and develop prosocial behavioral alternatives; (e) Cognitive, Behavioral, and Social Learning Theories (Bandura, 1969; Beck, 1976; Krumboltz & Thoresen, 1969, 1976), which advocate assessing the problem, developing goals for behavior change, and utilizing techniques such as cognitive restructuring, self-monitoring, reinforcement, modeling, and behavioral rehearsal to ameliorate the problem; and (f) Solution-Focused Therapy (deShazer, 1985; O'Hanlan & Weiner-Davis, 1989; Walter & Peller, 1992), with its focus on looking for "exceptions" in order to turn them into solutions.

According to more recent research, the majority of counseling groups in schools use a combined cognitive and behavioral approach (Barlow, Burlingame, & Fuhriman, 2000; Kulic, Hore, & Dagley, 2000). However, Shechtman (2002) suggested that to assume that cognitive–behavioral therapy is more effective than other approaches for working with groups in school settings is presumptuous to say the least. This may be the case simply because other approaches have not been the focus of frequent study.

Process and Outcome Research on Group Work in Schools

Of the dearth of literature on counseling groups in general, there is even less information available on group work in schools, which, of course, has led to the continued call from various entities for more research on the effectiveness of group counseling in schools (e. g., Jacobs, Masson, & Harvill, 2002). Among the studies that have been done, Burnham and Jackson (2000) found that 90% of school counselors conduct small groups in their school setting. This research and the few other studies available suggest that small group interventions in schools can be effective with a range of student issues. Among the issues where group work has demonstrated effectiveness are the areas of (a) interpersonal skills (Amerikaner & Summerlin, 2001; Ciechalski & Schmidt, 1995; Rosenthal, 1993; Shechtman, 1994); (b) family issues (Arman, 2000; Kizner, 1999; Omizo & Omizo 1987b; Tedder, Scherman, & Wantz, 1987); (c) aggression and other behavioral problems (Brake & Gerler, 1994; Omizo, Hershberger, & Omizo, 1988; Shechtman, 2000; Shechtman & Ben-David, 1999; Shechtman & Nachshol, 1996; Taylor, Liang, Tracy, Williams, & Seigle, 2002; Utay & Lampe, 1995; Verdyn, Lord, & Forrest, 1990); (d) academic achievement (Rowell & Hong, 2002; Shechtman, Gilat, Fos, & Flasher, 1996); (e) stress management (Brooks, 2004); (f) study/organizational skills (Cook & Kaffenberger, 2003); (g) self-esteem (DeLuca, Hazen, & Cutler, 1993; Hlongwane & Bason, 1990; Omizo et al., 1988; Riddle, Bergin, & Douzenis, 1997); (h) at-risk students (Blum & Jones, 1993; Ripley & Goodnough, 2001; Zinck & Littrell, 2000); (i) diversity issues (Bemak, Chi-Ying, & Siroskey-Sabdo, 2005; Bradley, 2001; Muller, 2000; Muller & Hartman, 1998; Reeder, Douzenis, & Bergin, 1997); (j) learning disabilities, ADHD, and gifted (Ciechalski & Schmidt; Omizo & Omizo, 1987a; Webb & Myrick, 2003); (k) improved attitudes (Myrick & Dixon, 1985); and (l) career (Barkhaus, Adair, Hoover, & Bolyard, 1985; Glaize & Myrick, 1984).

Limitations in the Research

Despite the previously cited research, one of the consistent criticisms of the literature in the field of group counseling in schools is the limited information on group counseling outcomes. Potential explanations for this phenomenon include the inherent difficulty in effectively measuring the complex dynamics of the group process. Another consideration is that much of the group work that is conducted occurs in school settings by school counselors, who do not have the time, the necessary training, or the inclination to conduct research on the groups they administer. Also, despite a general consensus in the existing literature that group counseling in schools is effective for children and adolescents (Hoag & Burlingame, 1997; Kulic et al., 2000; Shechtman, 2002; Whiston & Sexton, 1998) and as effective as individual counseling (Hoag & Burlingame; Shectman & Ben-David, 1999), narrative reviews point to a lack of sophistication and rigor in methodology (Hoag & Burlingame). It seems that there is a consensus that groups are effective, but specifics on what makes them so and evidence of overall impact are lacking in the literature (Shechtman, 2002). Shechtman further added that process research is particularly important for the continued development of theory in the area of group work with children and adolescents and is crucial to informing counselors about evidence-based practice.

Of the limited number of studies that have been conducted examining process variables in group work with youth, there is some indication that the process of group development departs to some extent from what research has shown with adults. For example, research with children has shown that the "working" stage of group development occurs very quickly, which is congruent with observations of children's openness and willingness to self-disclose (Shechtman, 2002). As for therapeutic factors identified in the adult literature, only two of those factors

were consistently found in work with adolescent groups—namely, catharsis and interpersonal learning (Shechtman, 2002). A third influential factor, which has rarely been found in research with adult groups, was social skill learning (Shechtman, 2002). This research provides further evidence that developmental factors play an important role in group work with youth and echoes a cautionary note about assuming that adult theories and models can be applied across the board with children and adolescents.

Additional Perspectives on Extant Research and Theory

While it is clear that a range of techniques from various theories has been applied in working with small groups in school settings, there is some concern, given the technological, demographic, and sociopolitical changes in society, that existing theories may fall short of being sufficient for working with students in the 21st century. This lack of preparedness to effectively deal with schools' changing demographics across the country leads to many students feeling isolated and alienated. This isolation, in turn, often leads to problems with truancy, classroom behavior, academic failure, and increased drop out rates. Shechtman (2002) suggested that what is needed is a theoretical model that accounts for children's and adolescents' needs for emotional expression, social connectedness, and practical support with problem issues.

While various developmental theories and traditional therapies such as Client-Centered Therapy, REBT, RT, Adlerian Therapy, and Cognitive and Behavioral Therapies have served as a foundation for working with children, adolescents, and adults throughout the 20th and into the 21st century, it is important to recognize that these perspectives may be limited in their abilities to adequately address the needs of a changing society. Some of these limitations have been discussed in the literature and include the observations that, for the most part, existing traditional theories (a) were based on societal and family dynamics from the previous century, (b) were developed for use in clinical settings, (c) reflect deep-seated Eurocentric perspectives, and (d) lack sensitivity to gender differences and diversity issues (Gilligan, 1982; Jordan et al., 1991; Stiver, 1991). Thus, new theories and models are desperately needed to address these concerns adequately. It is also important to remember that theories, while they are necessary supports to counseling, are a bit like cars—in need of constant care, maintenance, overhaul, and eventual trade-in. Because school counselors are dealing with issues and concerns unique to special populations, it is crucial to find, develop, and utilize theories conducive for working in school settings that are flexible and that provide for the consideration and appreciation of a range of contextual factors.

Diversity Competence: A Call for Contextual Models

Relational-cultural model. *Diversity* has been defined as "differences between people and the way we deal with those differences" (Jordan & Dooley, 2001, p. 23). These differences include, for example, age, gender, race, ethnicity, language, culture, class, exceptionalities, sexual orientation, gender identity, and geography and highlight perhaps the most important role of school counselors in the 21st century, that of advocate. While aspects of existing traditional theories may be adapted for use in working with groups on diversity issues, they do not provide a comprehensive base for addressing many students' special needs. A more recent theory that holds potential for working with these particular issues is the Relational–Cultural Model (Jordan et al., 1991; Miller, 1984). This model is based on the premise that human development and self-identity occur within a sociocultural context and that individuals "grow through action in relationship with others" (Walker, 2004, p. 4). According to the Relational–Cultural Model, authentic and mutual relational connections are necessary for optimal development, a premise that stands in contrast to more traditional models, which emphasize the importance of separation and individuation (Miller & Stiver, 1997). The Relational–Cultural Model's emphasis on mutuality and relatedness seems ideal for group counseling in schools in its ability to capitalize on the potential for building growth-fostering relationships in groups. As pointed out by Fedele (2004), "The ongoing process of connection, disconnection, and reconnection with the aim of enlarging relational possibilities is the very essence of group work" (p. 194). In this environment, members work and learn together about themselves and others in a climate of openness, mutual respect, appreciation, and support, thereby promoting opportunities for individual and collective empowerment.

One such group counseling program utilizing the Relational–Cultural Model, the Open Circle Competency Program (Wellesley Centers for Women, 2005), was developed for use with K–5 students, teachers, parents, and administrators. The program, based on social and emotional learning principles, reflects the Relational–Cultural Model's emphasis on the importance of relationships in fostering the academic, personal/social, and career success of children. It integrates the latest research on child development with evidence-based teaching practices and emphasizes concepts designed to build upon and reinforce each other as students move from grade to grade. The yearlong curriculum is presented in 15- to 30-minute sessions twice a week and covers the areas of active listening; self-calming;

assertiveness; coping with teasing, harassment, discrimination; and anger management. The training includes providing teachers, parents, and administrators with social competency and facilitation skills so that they can model and implement the strategies throughout the school setting and at home. To date, the Open Circle Competency Program has trained more than 5,600 teachers and counselors and has been implemented in public, private, parochial, urban, suburban, and rural school settings across New York, New Jersey, and New England (Wellesley Centers for Women).

Research thus far on the Open Circle curriculum has pointed to its usefulness in teaching relational and communication skills, addressing interpersonal issues, and assisting children and adolescents in feeling like part of the larger community. Studies by Black (1995) and Taylor et al. (2002) have revealed that students participating in this curriculum report improved self-worth; increased empathy, collaboration, mutuality, responsibility, and participation; and increased feelings of empowerment. Also, results showed some gender effects, with teachers reporting higher adjustment and assertiveness in girls, boys reporting improved self-control and fewer problems with fighting, and girls reporting improved adjustment (Taylor et al., 2002).

Applying the relational–cultural model. The following middle school case scenario is included in order to illustrate the application of the Relational–Cultural Model to group work in schools and to serve as a backdrop for the various "Group in Action" sequences that thread throughout the rest of the chapter.

Myer Middle School, consisting of grades 6 through 8, was constructed 20 years ago in a small bedroom community with a population of 6,000. Since that time, the community has tripled in size. Myer's enrollment has increased substantially, too, reflecting the growing diversity in the community. Currently, 64% of Myer's middle school students are identified as Caucasian, and 36% of the students are identified as one of several racial and ethnic minority groups. Given the rapidly changing demographic climate, Ms. Evans, the new school counselor, conducted a needs assessment among the students, teachers, parents, and administrators to identify salient issues for group counseling and classroom guidance. The feedback suggested a pressing need for working with students, teachers, parents, and administrators on diversity-related issues. As a result, Ms. Evans and the school's guidance advisory committee have worked to incorporate material on appreciating and respecting differences into the core guidance curriculum. Within this curriculum, a pilot, nine-session small group plan based on relational–cultural theory was developed for use with students in conjunction with an in-service workshop for school personnel and a PTA presentation for parents.

Flyers advertising the group were placed in various locations around the school campus. Several boys and girls were selected for prescreening interviews based on self, teacher, and/or parent referral, suggesting that these students seemed isolated and lacking in peer support. Interviews focused on explaining the purpose of the group, group goals, and group norms. A brief discussion covered issues of informed consent, privacy, and the importance of confidentiality and respect for other members. Potential participants were asked to sign a contract stating they would abide by the expectations for confidentiality. Parental permission forms were also distributed. Of the 10 students interviewed, 8 returned signed permission forms to participate in the group. Of the 8 participants, 4 were female and 4 were male; 5 were 7th graders and 3 were 8th graders. For 4 of the students, this was their 1st year at Myer. Of the students, 2 were African American, 2 were Asian American, 1 was biracial, 1 was Native American, and 2 were Hispanic/Latino. Arrangements were made with all teachers for the group to meet during alternate elective periods.

Multicultural responsiveness. With the increasingly diverse climate in society and public school systems, it is imperative that counselors attend to racial and ethnic diversity issues in their respective settings. Despite an increased call for multicultural competencies in education, there is much room for improvement in several important areas. For example, it is predicted that by the year 2020, ethnic minority students will make up 50% of the student body in public schools (Holcomb-McCoy, 2003). This stands in contrast to the fact that the majority of counselors in school settings are White females (Erford, House, & Martin, 2003). This underscores the responsibility of school counselors to be culturally responsive and competent (C. C. Lee, 2001; Locke, 2003). In this regard, Arredondo (1996) stated, "multicultural competencies were developed and defined to systematically address the centrality of culture, ethnicity, and race to counselor education, research, and practice" (p. 3). Research by Sodowsky, Taffe, Gutkin, and Wise (1994) revealed four multicultural competency areas for counselors: (a) multicultural counseling skills, (b) awareness (of life and professional experience levels), (c) counseling relationship (e.g., comfort with differences, sensitive to trust issues), and (d) counseling knowledge (e.g., see Roysircar, Arredondo, Fuertes, Ponterotto, & Toporek, 2003, for a more detailed discussion of multicultural counseling competencies). Thus, school counselors must begin with self-examination of personal biases and work toward recognizing the effects of oppression on students from minority populations, the privileges that the majority culture offers, and the existence and impact of overt and covert racism and discrimination. Utilizing input

from minority students, teachers, administrators, and families in developing the guidance curriculum and in making decisions that affect students is imperative for ensuring that counseling services provided in the school setting are responsive to individual students' needs.

Specific to the school setting, Locke (2003) suggested the following strategies are necessary for improving multicultural competence among educators:

- being open and honest in relationships with culturally diverse students, including talking positively with students about their traits, attributes, and cultural characteristics
- seeking out and possessing knowledge about one's own culture and background and how that impacts one's value and belief system
- recognizing and valuing different cultures and providing opportunities for students of various cultural groups to interact in a way to help them differentiate feelings of superiority from feelings of pride and self-worth
- utilizing opportunities to get involved in cultural groups in the community and finding ways to involve various cultural groups/organizations and leaders in the community in working to improve intergroup relationships
- working to balance views of students as members of a cultural group but also as unique human beings with individual differences
- challenging and eliminating personal biases and prejudices and doing the same with students, teachers, parents, and administrators
- working with school personnel to ensure that the school climate acknowledges the contributions of all racial and ethnic groups through mutually agreed upon solutions reflecting respect for differences
- maintaining consistent expectations for all students and providing opportunities for students to develop and value their self-identity
- recognizing the importance of students' cultural heritage by seeking out information on cultural diversity and sharing the information with students, teachers, parents, and administrators
- developing and implementing programs that foster cultural appreciation and being attuned to and eliminating practices that employ grouping procedures of racial and ethnically diverse groups

In applying these competencies to group counseling, counselors must have knowledge and awareness of both the impact of diversity-related factors on group work and how these factors may affect group participation and process. For instance, relevant diversity-related factors include (a) racial identity development (e.g., see Sue & Sue, 2003, for a more comprehensive discussion of racial identity development), (b) cultural influences on gender role expectations, (c) disclosure and privacy issues related to cultural norms (e.g., loss of face), (d) family or group (i.e., collectivistic) versus individualistic worldview orientation, and (e) acculturation conflicts, including ambivalence regarding balancing traditional and mainstream cultural values.

GROUP IN ACTION—MULTICULTURAL

Group goals and rules are briefly reviewed. Members introduce themselves using a "making connections" activity, which allows them to identify strengths and assets in themselves as well as in other members of the group. Members reflect on the concept of unity and the strength associated with being part of something bigger than themselves and how the group will become what each member is willing to bring to it. At this point, members suggest possible names for the group. A consensus is reached and the group is officially christened the X-Squad. Members like the idea that, much like in the X-Men comics, they all bring unique individual talents and strengths to the group. Next Ms. Evans, the school counselor, tosses a loose ball of yarn into the center of the group circle and asks each member to identify of what the pile of yarn looks like. After summarizing the different views, a discussion follows with several group members talking about advantages in "seeing things differently." Ms. Evans takes this opportunity to encourage Christina, an Asian American student, to join the discussion. She haltingly begins to talk about how she struggles with conflicts between her parents' expectations and the expectations of her teachers and some of her peers. Her parents push her to excel in school and to observe traditional customs, while her teachers and some of her friends encourage her not to push herself so hard academically and, instead, to be more socially active. She explains that it is hard for her to talk about these conflicts because her parents expect such issues to be dealt with privately. She adds that she feels "different" and confused a lot of the time and just wants to be able to be more like the other students at Myer so she can fit in. It is obvious from the reaction that some of the other group members share Christina's struggle, and Ms. Evans makes a mental note to follow up in the next group session with an activity to stimulate more discussion related to issues of acculturation and racial identity development.

Other Diversity Issues

Sexual harassment. Ample opportunities also exist in schools for group work with other areas of diversity. For example, the authors' experience, which is supported in

the literature, is that group work in schools related to sexual harassment is almost nonexistent. Despite the fact that sexual harassment issues in schools have received some media attention since the 1990s, it continues to be a serious problem in educational settings as evidenced by research that suggests that 90% of all sexual harassment incidents in schools go unreported (American Association of University Women [AAUW] Educational Foundation, 2001).

The U.S. Department of Education, Office of Civil Rights (1997) has defined sexual harassment as "sufficiently severe, persistent, or pervasive (behavior) that adversely affects a student's education or creates a hostile or abusive educational environment and the conduct must be sexual in nature" (p. 12036). According to Stone (2004), sexual harassment may also be recognized by examining whether

> the behavior is unwanted or unwelcome, the behavior is sexual or related to the gender of the person, and the behavior occurs in the context of a relationship where one person has more power, such as the informal power one student can have over another. (p. 354)

The AAUW defined sexual harassment as "unwanted and unwelcome sexual attention that interferes with your life" (AAUW Educational Foundation, 2001, p. 2) in their study, *Hostile Hallways*. This study revealed that 83% of girls and 79% of boys have been sexually harassed in a school setting. Although victims of harassment were both male and female, girls were represented in greater numbers and suffered from more negative consequences (AAUW Educational Foundation; Fineran & Bennett, 1999; Hand & Sanchez, 2000; V. E. Lee, Croninger, Linn, & Chen, 1996; Timmerman, 2003). More recently, the Supreme Court has weighed in on the issue of sexual harassment in schools via *Davis v. Monroe County Board of Education* (1999). The ruling in this case stated, "public schools can be forced to pay damages for failing to stop student-on-student sexual harassment" (Stone, 2004, p. 355), providing a wake-up call to schools as to the extent of their responsibility in implementing a zero tolerance policy related to incidents of sexual harassment.

GROUP IN ACTION—SEXUAL HARASSMENT

The group begins with Ms. Evans asking the members to define *sexual harassment*. Once the group has reached an agreement on a working definition, members are asked to pair up to review several scenarios describing potential sexual harassment of males and females. Next, the group members are asked to move to the floor in a tight circle. Ms. Evans places a plastic bucket in the center of the circle within everyone's reach. She hands out a cup full of water to each member. Then she begins to read several statements related to harassment. For example, "Have you been teased or called names" and "Have you ever been embarrassed by suggestive comments?" She asks the members to pour out some of their water into the center bucket every time they have had a similar experience. At the end, each member is asked to look at his or her "self-worth" cup and to reflect on how harassment affects his or her self-esteem.

Sexual orientation and gender identity. Information about group counseling interventions focused on exploring sexual orientation (i.e., "an enduring emotional, romantic, sexual, or affectional attraction toward others," [APA, 2004, ¶. 1]), gender identity (i.e., "the psychological sense of being male or female," ¶ 1), and social gender role (i.e., "adherence to cultural norms for feminine and masculine behavior," ¶. 1) issues are even more underrepresented in the school counseling literature, no doubt because these subjects have long been considered taboo in school settings. Ignorance, fear, and denial around these issues makes work with gay, lesbian, bisexual, transgendered, and questioning (GLBTQ) students especially challenging. For the most part, the needs of GLBTQ students have been neglected by school systems. Students from these groups have been at best ignored and at worst teased, harassed, and physically assaulted. A survey conducted by the Gay, Lesbian, and Straight Education Network (1999) revealed that 59% of GLBTQ youth were verbally harassed or physically attacked; 50% reported being harassed daily. In addition to harassment from their peers, many of these young people experience ridicule and/or abuse from family members. Although some schools would like to believe that students from these groups are not represented in their settings, the reality is that every school likely has at least one and probably more GLBTQ students. Many students do not reveal their orientation or questions for fear of rejection or physical assault. The other harsh reality is that because of their plight, these students often cope by socially isolating, abusing alcohol and drugs, engaging in risky and/or indiscriminant sex, and acting on suicidal impulses (Ryan & Futterman, 1998).

GROUP IN ACTION—SEXUAL ORIENTATION, GENDER IDENTITY, GENDER ROLES

The group begins with a review of the previous session, which focused on an activity designed to spur a discussion of the "realities" of being heterosexual versus homosexual and male versus female in today's society and, more specifically, in Myer Middle School. Next, Ms. Evans asks the members to move to a large

table with various materials for making paper masks. She asks the members to make two masks, one for the way they think others see them and one for how they see themselves.

When everyone is finished, members discuss feelings and experiences related to having others "fail to see" them and whether "wearing a mask" is good or bad. One group member, Susan, brings up the example of people who act tough in order to protect themselves from getting hurt and how this can backfire and keep people from wanting to connect with them.

Making it Happen—Practical Considerations in Group Work

First Steps

As has been demonstrated by the limited research, small group counseling in schools represents a viable conduit through which to address a range of issues and concerns for students, teachers, administrators, and parents. To facilitate effective groups, however, school counselors must have an understanding of theory, diversity issues, and training in leadership skills, including not only group leadership skills but also skills for marketing group interventions. This would include, more specifically, background and training in how developmental theory works in conjunction with counseling theory to promote personal growth across different age and grade levels. Counselors must be knowledgeable in a variety of content areas and have training in and an understanding of the purposes of groups and processes related to optimal group functioning in order to be able to effectively utilize these skills to improve student performance. Finally, they must possess self-awareness and knowledge of how contextual factors influence student functioning and skills grounded in theory and research that accurately reflect the many nuances of diversity.

Building support and assessing need. Educating stakeholders such as teachers, administrators, and parents on how groups can effectively support and enhance students' academic, personal/social, and career achievement and promote the mission of the school is an important first step. This may be accomplished in various ways. For example, orientation programs presented at staff development workshops, parent support organizations, and regular faculty meetings can be used to inform and solicit program support from internal and external entities. Creating guidance curriculum advisory committees comprising teachers, administrators, parents, students, and community/business leaders to work together to develop and plan comprehensive guidance curricula is another excellent way to get much needed support for guidance and group counseling. Once support for group services is procured, the next step is conducting a needs assessment (Davis, 2005; Jacobs & Schimmel, 2005; Studer, 2005). Needs assessments can be administered formally by sending out short surveys or checklists to students, teachers, administrators, and parents, asking them for feedback on the kinds of groups they think would be helpful and informally by observing changes in the school climate and by talking with students, parents, and teachers about recurring problems. Once this information is collected, it is shared with members of the guidance advisory committee. Then the committee can use the data to prioritize needs and plan what types of groups should be offered to students in that setting.

Utilizing a knowledge base. Group dynamics are complex, and knowledge of group stages, group processes, and facilitative skills are crucial to the effective functioning of the group (Schmidt, 1999; Sciarra, 2004; Studer, 2005). Most of the literature on group processes pertains to adults, but a few studies have looked at group counseling with children and adolescents (e.g., Shechtman, 2002). While some differences in processes and group stages have been found with younger group members, in general, the dynamics tend to be quite similar.

The four stages of group involvement identified by Myrick (2003) are (a) involvement, (b) transition, (c) working, and (d) ending. The involvement stage is characterized by group members getting to know one another, establishing appropriate rules for the group, discussing the importance of confidentiality, and laying the necessary groundwork for building trust within a safe, supportive environment. The following brief excerpt illustrates the involvement stage:

> "Hello and welcome to the group. We hope that this group will allow you to talk about your experiences at Myer. We are going to be together for the next 9 weeks to help you get to know and respect yourselves and others better and to learn about connecting in relationships and about how to handle conflict (disconnection) in relationships. To do this, everyone must try to support and encourage each other and be open to new and different ways of thinking, feeling, and looking at the world. As we talked about earlier, what we discuss in the group is confidential and should not be shared with anyone outside the group. Does anyone have any questions?"

In the transition stage, members are learning to trust and work together. It is generally characterized by the beginnings of self-awareness and insight into behaviors evidenced

by tentative self-disclosure and feedback from members. During this stage, group members begin to connect around their similarities and to recognize and talk about their differences (Fedele, 2004), similar to the following scenario:

> "Last week, toward the end of the group session, Lena was talking about how hard it is to be a new student at Myer this year. John and Keisha added that, although they've been at Myer since 6th grade, they still don't feel "accepted" by the other students. Others of you also expressed similar feelings. Let's begin today by talking more about how the lack of connections with others affects each of you and see whether your experiences with this are similar or different." As the group members begin to describe their feelings of disconnection and isolation in more detail, Lena comments that, for her, the worst part is the "loneliness." Several other members agree that they, too, feel lonely, and the group begins to join around the shared experiences of several of the members.

The working stage occurs once members develop trust and are comfortable enough to self-disclose and provide constructive feedback to other group members. This stage is characterized by deeper investment in the group and the confidence to try out new skills and behaviors. An important aspect is the emerging of conflict and disconnection and the willingness to work through it, for example, to "make and hold connections between apparent opposites" (Fedele, 2004, p. 205). An example of group dynamics during this stage is illustrated by the following:

> "The last time we met, several of you talked about your feelings of disconnection and loneliness. In doing that, some of you were able to connect around others' shared feelings and experiences. I noticed, however, that a couple of you were silent about your own experiences and instead focused on advising other group members what they should do to 'get through the day.' I sensed some tension in this process, and I would like to start by talking about what might be going on here."

Finally, the ending stage is focused on how to apply what has been learned in the group to other settings. New emotions and concerns may surface around "losing" access to the relational process and authentic connections formed in the group at this point. It is important in this stage for school counselors to acknowledge these concerns and allow members to vent their feelings so that they can be processed effectively. Emphasis on summarizing progress in the group and focusing on where members are headed can often allay many of these fears. The final stage of the group process might look something like the following:

> "We've been preparing for this day for a couple of weeks now. I'd like to begin by having everyone share a little about what the group experience has been like for them, what you've learned about yourself and others, and how you can use what you've learned about relationships to help you in the future." During this process, Christina says that being in the group has helped her to feel better about "things," but she is worried that once she is away from the group, everything will just go back to the way it was. Other members are able to point out to her that even though the group won't be meeting together, they will still have some classes together and see each other at lunch and sometimes after school. They remind Christina that she has started to make a couple of new friends outside of the group as a result of what she learned about connecting with other group members and that she can use what she's learned about herself and others to build new relationships and to work through problems and conflict in current relationships.

Who Is Your Audience? Issues Related to Development and Geographical Locale

Groups for elementary students. One strength of small group counseling is that the format can be used with students of all ages from elementary school to high school and in rural, urban, and suburban locales. Elementary schools are especially conducive to group work because the classes tend to be self-contained, providing easier access to students and the opportunity to get to know students and their particular needs. Also, elementary counselors tend not to be responsible for time-consuming duties such as scheduling, record keeping, and preparation for high school and college. The early years of elementary school are also a crucial developmental period for children. Their identities, values, attitudes, and beliefs are just beginning to form. They are starting to acquire social skills, and they are eager and enthusiastic about learning and pleasing those around them. Even during these early years, however, children are susceptible to peer influence and can often learn better by watching others (Davis, 2005). Groups allow this observational learning and help young children to understand their feelings and emotions, which can sometimes be confusing, frustrating, frightening, and overwhelming. Counseling in groups provides young children with modeling, skill building opportunities, and support in a

safe, nonjudgmental environment. Topical groups that are appropriate for young children include building authentic and mutual connections with others, communicating, dealing with ADHD symptoms, anger management, study skills, coping with loss, parental divorce, behavior problems, and achievement issues.

Groups for middle school/junior high. The middle school/junior high years are challenging. Adolescents in this period are struggling with asserting their autonomy, while still wrestling with their needs to be dependent. Puberty, with its hormonal changes, can be a confusing, frightening, and frustrating time for some youth. Moods may fluctuate, and because their bodies are growing and changing so rapidly, adolescents may feel awkward, gawky, and clumsy, which may have a negative impact on their sense of self-worth. On a developmental note, groups with adolescents tend to be more complex as students become better at communicating, expressing emotions, and abstract thinking. Counseling at this age can provide opportunities for increasing problem-solving and decision-making skills; promoting awareness, appreciation, and acceptance of difference; improving communication and self-worth; learning to hold on to connection while working through conflict (Fedele, 2004); and experiencing mutual empathy and "power with" (Surrey, 1991, p. 165) another. Groups also capitalize on the influence of peers and pressures to conform in constructive ways. In groups, adolescents can help each other learn and practice new skills and behaviors, deal with peer pressure, work through identity issues, and manage stress.

Groups for high school. High school students are also prone to experiencing multiple stressors. Pressures from peers and parents as well as expectations for college and career may weigh heavily on older adolescents. At this age, students are still learning about interdependence and testing the limits of their independence. They are faced with having to make many important decisions and are learning to use their relational networks in new ways as they practice solving their problems. Groups at the high school level tend to focus on issues such as romantic relationships, substance use, sexuality, body image, teen parenting, stress management, family issues, peer influence, diversity and identity issues, and college and/or career planning.

Groups and geographical considerations. According to the U.S. Department of Education's Office of the Deputy Secretary (2003), approximately 43% of all schools are classified as rural, and rural schools educate nearly one third of all students in the United States. Preconceived notions about the differences in rural, urban, and suburban schools are common. For example, while rural schools may be viewed as being located in poor, backward, agricultural communities, they may also be viewed as safer and less prone to crime and violence. In contrast, it may be assumed that urban schools are fraught with issues related to poverty and lack of resources, such as lower academic achievement, truancy, higher dropout rates, increased behavioral problems, and student violence. Somewhere in the middle, of course, are the suburban school settings, which, to some, may appear idyllic in their perceived insulation from crime and poverty and in their access to supportive community resources. Obviously, the reality is that schools, whether rural, urban, or suburban, struggle with many of the same problems, and all have their own particular strengths and weaknesses.

It is true, however, that group work in more isolated rural educational settings can be hindered by a variety of factors, including limitations in the facility (e.g., older, cramped buildings) and lack of tax-based funding and supplemental community resources (Hines, 2002). At a minimum, counselors must possess both awareness and knowledge of the local culture in order to help facilitate effective groups. Furthermore, although rural students may have a strong sense of community and connection and an accessible support system, they may experience considerable social, cultural, and academic isolation and may be quite anxious about making academic, career, and life decisions (Gibbs, 2000). Thus, counselors doing group work in rural settings must capitalize on community-based strengths by cultivating ongoing partnerships with business, industry, and professional organizations. Partnerships such as these can provide a foundation for exploring additional resources and opportunities for students and promote a collaborative vision of the school as an extension of the community and the larger society. This reality echoes, once again, the importance of developing and utilizing brief surveys to elicit feedback on the needs of rural, suburban, and urban schools in order for group work to be a viable guidance program adjunct in addressing the unique issues in each setting.

Decisions to Make

What type of group to offer. Groups conducted in schools tend to fall into two categories—namely, psycho-educational or counseling. Within these categories, the format for groups may be open, allowing members to enter and leave the group at any time, or closed, requiring all the members to begin and end the group process together. Many school groups tend to be closed because having students enter and leave the group at different points can interfere with natural group processes such as building trust, connecting, and disclosing. Some groups, however, might be conducive to an open format. For example, an ongoing group to orient new students to the school could run year round,

with new students entering the group until they have the lay of the land and leaving once they feel that they can function on their own.

Groups may also be homogenous or heterogeneous. Homogenous groups are composed of members who share very similar characteristics, such as age, grade, SES, race, ethnicity, gender, and/or sexual orientation. Heterogeneous groups are composed of members with widely varying characteristics. The purpose of the group is a key factor in, for example, deciding the question of group composition. For instance, if the group is designed to be more supportive in nature and to foster healing and growth through universality, then homogenous membership may work better. Having other students with the same characteristics and similar experiences and concerns creates a sense of understanding and acceptance. If the purpose of the group is to challenge perspectives and to promote learning through relational modeling and peer influence, then heterogeneous groups are a better fit. In groups with a remedial focus, heterogeneity among the members provides positive modeling; challenges existing perspectives; and offers opportunities for mutual feedback, peer influence, and relational learning. Ritchie and Huss (2000) suggested that heterogeneous groups are superior because they include a mix of students with and without specific problems and they can be designed to be supportive, preventative, or remedial in their focus. Perhaps this is because of the differences and, sometimes, the conflict that occurs in a heterogeneous group. From the perspective of the Relational–Cultural Model, conflict offers a relational opportunity: "In the larger picture, building bridges means confronting prejudices rather than ignoring them to create an illusion of solidarity" (Fedele, 2004, p. 205).

Size, frequency, duration, and location. The size of the group depends on various conditions (e.g., age, purpose). Most experts agree that 5 to 8 members, with smaller numbers for groups with very young children and larger numbers for adolescents (e.g., Myrick, 2003), are ideal. Corey (2000) suggested the rule of thumb should be, "the group should have enough people to afford ample interaction so that it doesn't drag and yet be small enough to give everyone a chance to participate frequently without, however, losing the sense of the 'group'" (p. 90). Groups usually meet once a week for 6 to 12 weeks. The length of the group time differs with developmental considerations. Younger children have shorter attention spans, so 20- to 30-minute sessions are generally recommended. Because the group sessions are shorter, some groups for younger children may meet twice a week. For adolescent groups, sessions usually correspond to one class period (approximately an hour in most cases).

Finding an appropriate place to meet in order to ensure confidentiality and privacy can often be a challenge because many schools lack a surplus of space. When to schedule group meetings, however, is probably the biggest challenge. Teacher and administrator opposition to group counseling often hinges around the issue of students missing class and instructional time to participate in the group. Another concern that may arise with group work has to do with students returning to class upset over something that transpired in the group. Nevertheless, there are creative ways around these sticky issues. For instance, groups can be organized around a rotating schedule so that students do not miss the same class every week. In some school settings, group meetings can be held during homeroom, study hall, or lunchtime. Also, counselors should be prepared for the need to help individual group members decompress after highly charged group work.

Who's right for the group? Members can be recruited through self-, teacher, or parent referral. Once potential members are identified, it is vitally important to have a screening procedure in place to determine if the student is appropriate for the proposed group. Unfortunately, as important as groups are to a comprehensive developmental guidance program, they are not suited to working with students with severe problems. In this case, referrals to outside agencies or private practitioners who specialize in working with children and adolescents with serious behavioral disorders should be made.

Other purposes of the screening process are to give potential members information about the group goals and the expectations for participation and to get a sense of how each student may function in the group. Although the screening process requires another time commitment for the school counselor, it will save time in the end by allowing an opportunity to assess whether a student will be able to work effectively in or be a hindrance to the group process.

Once the members for the group have been selected, a letter with information about the group purpose and goals and seeking signed permission for student participation should be sent to parents. Another way to handle getting parental permission is to present a counseling program orientation for parents at a beginning of the year. Here, you can provide parents with information and materials on different groups that will be offered. Counselors may want to include a brief form for parents to sign if they do not want their son or daughter to participate in any type of group work in the school setting.

It Finally Begins: Leading the Group

In order to facilitate group work in school settings, school counselors must be trained in developing leadership skills.

These skills are crucial to guiding the group process and include basic skills such as communicating effectively, active listening, observing, modeling, questioning, challenging, problem solving, interpreting, supporting, linking, and summarizing. In addition, the school counselor must pay special attention to several key aspects of group leadership: (a) creating a safe and consistent relational place, (b) being present, (c) pushing the envelope, and (d) promoting altruism.

Creating a safe and consistent relational place. It is important for school counselors to clarify expectations and boundaries related to the group process (Fedele, 2004). In contrast to traditional models, however, boundaries are not understood as rigid lines of demarcation, but emphasize mutuality, genuineness, and respect and exist within a context defined by the members (Jordan, 2000). This emphasis is consistent with the Relational–Cultural Model and the group goal of "enlarging relational possibilities" (Fedele, 2004, p. 194). This focus on flexibility in allowing group members to express what they need in order to make the group work helps to provide a safe environment in which to meet and interact. It also helps reduce the negative effects of power differentials resulting from social hierarchies among students, with its emphasis on "power with" versus "power over" (Surrey, 1991).

Assertively communicating information about the roles in group work and what is expected helps to set the stage for more proactive participation among members. Likewise, dealing with behavior problems and enforcing mutually agreed upon group rules in a consistent, forthright manner communicates the importance of group work conveys a respect for group members' abilities to accept responsibility, and it assists the leader in helping members connect more effectively and authentically with each other.

Creating a safe and consistent relational space (Fedele, 2004) in the group also includes confidentiality. While counselors are ethically bound to protect the confidentiality of every person in the group (American Counseling Association, 1995; ASCA, 1998), there is no guarantee that members of the group will take this commitment as seriously. With this caveat in mind, the counselor must do his or her best to emphasize the importance of maintaining confidentiality during the screening process, in the first session as group rules are being developed, and thereafter as necessary. In addition, counselors may want to provide potential members with a written statement outlining the parameters of confidentiality before allowing individuals to participate in the group.

Ms. Evans, the counselor, welcomes everyone to the group and begins by reviewing the purpose and rules of the group and their commitment to confidentiality. Members then begin a "getting to know" you activity. Here members are provided one large and several smaller strips of construction paper to create a "unity chain." First, the students sign their names on a large strip. Then, each student is instructed to write the names of people in their lives that they feel connected to on each of the smaller strips, using as many as they need. The small strips are stapled together to form links in a chain for each student. Finally, all the "connection" chains are attached to the larger circle containing the names of everyone in the group. The completed "unity chain" is fastened to the wall of the group meeting room as a reminder of the members commitment to each other and the group.

Being present. Observation and active listening are key to keeping the group on task and moving the members in the appropriate direction toward a specified goal. Collectively, these skills also help to capitalize on positive aspects of peer influence and promote mutuality through openness to change and connection with others. They allow the group leader to take note of important comments, recognize patterns of connection and disconnection, model moving through conflict and disconnection back into reconnection, and model good listening skills to group members. This modeling is an important leadership skill in that it allows group members to see the leader and other members demonstrate appropriate behavior.

Over the last two weeks, Ms. Evans has observed several of the group members moving toward connection. As might be expected, some members have been more open in their disclosure in the group, while others still seem suspicious and tentative in their interactions. In order to create a climate for more open discussion, the counselor provides each member with a large piece of butcher paper and instructs all to create a map of their lives, including drawing in places and people that have special meaning for them. Once the maps are complete, Ms. Evans demonstrates how members will use their personal maps to give the others a "tour" of their world.

Pushing the envelope. From the perspective of the Relational–Cultural Model, an important relational goal is to teach youth to "value conflict as an opportunity for greater connection" (Dooley & Fedele, 2004, p. 243). Thus, exploration of conflict and challenging students to understand others' perspectives can be used to take the group process to a new level, increase ownership of feelings and vulnerabilities, and assist members in the development of empathy

toward feelings and vulnerabilities in others. Challenging can be used to encourage exploration of inconsistencies in group members' comments and behaviors, and discrepancies among what they are thinking, feeling, and doing. In addition, questioning and probing can be used effectively to clarify comments and solicit more information from members. This, in turn, can stimulate discussion that is more productive and allow for more breadth and depth in exploring problems and concerns. Last, interpretation helps group members better understand the potential causes for their problems and can stimulate self-awareness and insight. On a cautionary note, interpretations are really just educated guesses and, as such, should be done tentatively and respectfully and in a way that enhances mutual communication, allowing the group member to process and respond as to whether the speculation is indeed a good fit. In addition, it is essential that interpretations be congruent with the developmental level of the child or adolescent.

The group has been making good progress, but the last session was characterized by some silence and tension. Ms. Evans asks the group to sit in a tight circle on the floor. She places a large plastic ring with different-colored crepe paper streamers tied to it to represent the united group. Next she assigns each member a color. She explains that she is going to read several statements about different experiences and situations and asks the members to pull off a streamer in their color when the statement applies to them. For example, "When I speak up in group I feel like some people are judging me"; "Sometimes when people share advice, it reminds me of my mom, dad, or my teachers"; and "I'm not sure if I can really trust everyone in the group." At the end of the activity, students are asked to check how many of their streamers are still connected to the center ring. The counselor then asks the group to talk about what has happened. Students are encouraged to discuss their feelings of connection and disconnection.

Promoting altruism. Linking is a technique that allows the group leader, through active listening, to tie together what has been said by different members. It can be used to make important thematic connections within the group process, promote increased self-clarity and clarity about others, and create a sense of community by highlighting similarities in thinking, feeling, and experiencing. In addition, these connections free up members to help one another. Problem solving is useful for encouraging individual members to think about their own or other group members' situations or concerns in different ways, generating options, and encouraging other members to weigh in on how they would handle or have handled similar problems. Fostering this type of mutual empathy is important to the group process. Providing and capitalizing on opportunities for students to encourage and support each other and problem solve is crucial for establishing cohesiveness and trust, the glue of the group process.

"Last week, Susan talked about how her mom is "breathing down her neck" all of the time wanting information about where she is going and who she is hanging out with. The constant questions make Susan feel like her mom doesn't trust her. Can any of you relate to her experience at home? If so, how have you tried to handle the situation?" Several group members take turns speaking up about their own situations at home and about how they deal with rules. Tony and Keisha, in particular, suggest potential ways for Susan to negotiate on issues and ideas she might try to gradually earn more parental trust. Jonah, who tends to be very quiet, begins talking about how his mother works two jobs and is so tired when she gets home that she doesn't even seem to care what he's been doing or who he's been hanging out with. Group members, again, respond with concern and support and begin to help Jonah problem solve ways that he can connect with and communicate feelings to his mother.

Evaluation of Group Work and Commitment to Accountability

Merely conducting group activities in school settings does not ensure that they will be effective. Group practices should be rigorously tested and processes should be explored to demonstrate their effectiveness in accordance with evidence-based practices (APA, 2005). In light of the most recent educational reforms such as the *No Child Left Behind Act* (U.S. Department of Education, 2002), school counselors, along with their teaching colleagues, must be able to demonstrate accountability. They must commit to demonstrating that the services they provide have a positive impact on the students they serve. This may prove to be a difficult challenge for several reasons: (a) lack of training in research and evaluation; (b) lack of available time for school counselors to conduct research, given that studies have shown counselors often spend time performing duties that are inappropriate (i.e., record keeping, clerical work, substitute teaching, etc.; e.g., Ober & Beesley, 2004); and (c) reluctance on the part of school counselors to conduct research due to a lack of self-efficacy in this area. For these reasons and others, school counselor training programs must provide opportunities for counselors in training to develop and conduct needs assessments and to

collect outcome data on the groups they facilitate in order to evaluate their effectiveness in working with students.

One possible way to stimulate this kind of accountability would be to require regular reports on group program status using readily available data (e.g., attendance, grades, achievement testing, number of discipline referrals) to demonstrate the positive impact of group counseling on the achievement and functioning of all students. These reports could be disseminated in school newsletters, on school Web sites, and in packet form for presentations at school board, parent organizational, and faculty meetings. Demonstrating that groups work with children and adolescents in school settings will do much to encourage support from teachers, administrators, and parents. In addition, helping counselors recognize that they already use data (e.g., attendance, grades, test scores) to advocate for students may help allay some of the anxiety about evaluation and accountability issues. Finally, the survival of the profession may depend on counselors' being able to consistently demonstrate that what they do makes a positive difference in the lives of all of their students.

Final Thoughts and Future Directions

Although research suggests that group work in school settings with children and adolescents is effective, the studies are limited in number and often not reflective of rigorous research methods. Also, concerns exist about the ability of traditional theoretical models to conceptualize issues related to our rapidly changing society. This has resulted in a call both for using theoretical perspectives that more accurately capture and reflect the complexities of contextual influences and for the development of new theories of group counseling. One such model that shows promise for use in school settings is the Relational–Cultural Model (Wellesley Centers for Women, 2005).

Group work in school settings serves as a centerpiece for a comprehensive developmental guidance program. It is not, however, without considerable challenges. To facilitate groups in schools successfully, counselors must have appropriate training in leadership skills, group process skills, research, evaluation, and diversity competence. It is not enough for school counselors to conduct groups for the benefit of all of the students they serve; they must also be committed to evaluating group outcomes to demonstrate the effectiveness of their work with children and adolescents.

XXIX
FAMILIES IN CONTEXT: An Essential Component of School Counseling

TERENCE PATTERSON
University of San Francisco

Introduction

Before delving into the realities faced by school counselors in the complex environment of today's schools, let us establish a framework for viewing the role of families: historically, conceptually, professionally, and practically.

On a practical level, the profession of social work recognized the centrality of families with the establishment of settlement houses such as Jane Adam's Hull House in Chicago in 1889 (Lissak, 1989). Serving many functions in the lives of immigrants and low-income city residents, the settlement house provided a refuge and a resource for those in need, and designed programs to involve parents in their children's activities, to keep families active and intact, and to assist those in need. As families moved out to more remote areas of cities and suburbs, those efforts evolved into the Family Service Association (FSA) of America, which provided services both centrally and in the home itself in order to accommodate changing living and family patterns. In the center and in the home, social workers engaged in social casework (Robinson, 1962), which involved connecting individuals and families with concrete services and also providing counseling, which might be seen as an early form of family therapy, and later became known as "clinical social work."

Thus the first family counselors (*therapist* and *counselor* will be used interchangeably) were social workers, and other mental health professionals did not recognize the essential role of families in intervention until the late 1940s and 50s. First a form of "family group therapy" (Bell, 1963), then "family network therapy" (Attneave, 1974), and "child guidance" (Levy, 1968) were identified, until "conjoint family therapy" (Satir, 1983) became the norm. The last became the standard for family therapists of all disciplines, including psychology, psychiatry, social work, nursing, counseling, and the profession of family therapy itself, and involves a counselor treating the entire family as a unit. Recent models, acknowledging the realities of modern life, include counseling family members both together and separately within a systemic context.

School professionals have long known that in every dimension, it is wise and necessary to involve parents and families in the life of the school. Thus, physical and mental health clinics were established in schools in the 1980s, providing both convenience and outreach for students and their families. Health providers and counselors not only began to come to the schools, but the schools were inviting the community, primarily families, into the school as part of a system of comprehensive, integrative services.

Theory

We now turn to the question, "What theories and developmental perspectives can serve as a foundation for comprehensive school counseling today?" The first element is General Systems Theory (GST; von Bertalanffy, 1968), which, in essence, views biological and social units as interacting elements that mutually influence each other. Major premises of GST are that systems have their own structure and processes; that a ripple in one part of a system can become a wave in the others, and each component has the potential of changing the entire system; and that systems cannot remain static, but must change or dissolve. GST was derived from the biological and physical sciences, was later applied to social science, and has become integrated into family psychology and therapy and, to a lesser extent, into organizational development.

For schools, the major elements are students, teachers, administrators and policymakers, staff, families, and the

community. A school is a system in itself, but has subsystems within it and is itself a subsystem of a school district and the larger community, nation, and world. Thus, federal and state education policies affect local schools and communities, and developments in schools such as violence and test results affect state and local policies and funding.

GST also refers to closed systems and open systems that are regulated by feedback (i.e., communication), and indicates that an open system has boundaries that are somewhat permeable and allow for the exchange of information with the outside so that the system can remain viable. Closed systems, on the contrary, have rigid boundaries and poor communication, and they lead to chaos and disorganization. In schools, this points to the need for clear structures and a free flow of communication, both internally with teachers, counselors, administrators, and students, and externally with the larger community, so that mutual understanding and decision making can occur within the school and among the home, school, and community.

A related, still-relevant concept began in the early 1960s when President Kennedy initiated the community mental health movement, in which not only were facilities in each local area designed to provide emergency and rehabilitative psychological programs, but *community education and prevention services* were included to coordinate networks of services in order to prevent social and mental health problems from occurring (Caplan, 1964; Cutler & Huffine, 2004). Although never fully funded, some model centers developed school–family–business–nonprofit partnerships involving parents and residents in decision making and in assisting children, parents, and educators to focus on the central mission of educating and socializing children in a stable environment.

Also in the mental health field, the family therapy movement took root in the '50s and '60s, first with the concept of *family group therapy* (Bell, 1963), in which families with similar needs were brought together in a large group to share experiences and solve problems. A related process, *family network therapy* (Attneave, 1974), was based in Native American communities and incorporated the tradition of bringing together significant community members, including elders, to deal with family issues. Most recently, the concept of *ecosystemic therapy* (e.g., McDaniel, Lusterman, & Philpot, 2001) recognizes the interrelatedness of religious, educational, recreational, health, law enforcement, and other key institutions in providing comprehensive, integrated, stable environments for families.

Most mental health therapists and counselors who practice from a systems or family perspective recognize the need for significant others in a child or adolescent's life to be involved when problems arise, if not for intervention, at least for assessment. Thus, the *conjoint therapy* model, in which as many family or other individuals as possible are involved in treatment, is most desirable. Similarly, school personnel who refer to counselors understand the vital role that family members, relatives, and others in the community play in students' lives, but time often interferes with taking an approach that involves families and community members, and thus, solutions often become partial and inadequate. In this brief review of the foundations of family involvement, it is hoped that counselors and others will recognize the essential importance of including families in all aspects of working with students, and internalize the concept that it truly "takes a village" to raise and nurture children in a complex, changing environment.

Over the last two decades in particular, concepts and practices involving *multicultural competence* and diversity have informed practitioners of the advisability and necessity of taking culture, values, and traditions into account in engaging, assessing, and intervening with individuals and families. Most school counselors understand the critical importance of not only understanding the entire context of students' lives in assisting them appropriately, but of taking into account the individuality of each student and family, perhaps an even more difficult task. Concepts involving respect for elders, extended families, and alternative family forms, rituals, *personalismo*, and *familismo* (Falicov, 1998) have become integrated in counseling practice and have provided valuable lessons for all who work with families. The vital role of diversity will be examined in detail in the case example later in this chapter and in recommendations for the future.

Research

Many counselors' eyes instantly gloss over when scholarly research is mentioned. Let us briefly examine the reasons for this and present some practical examples of research that are directly useful in practice today. Psychoanalytic theories dominated the mental health field for the first half of the century and were largely theoretical and based on major disorders; that is, they were often derived from observations and clinical treatment of severely disturbed individuals in large treatment facilities. In addition, samples were usually small or uncontrolled for sources of variance. Following the 1950s, newer approaches began to appeal to the growing numbers of counselors who did not find traditional psychoanalytic models relevant to their practices. By the 1980s, many of the popular models of counseling were based on the writing and demonstrations of charismatic and leading-edge thinkers and clinicians, and research rarely involved systematic procedures or large samples from actual practice. Humanistic approaches to counseling and psychotherapy, including those of Carl

Rogers, Rollo May, and Abraham Maslow, attracted many. Behavioral techniques, although not popular in concept often because of inadequate explanation or misrepresentation, were often integrated into community counseling programs and agencies along with humanistic concepts, and they resulted in more practical approaches to counseling in neighborhood agencies and schools.

During the 1970s, psychotherapy and counseling practices came into vogue that involved two new, fundamental elements. First, clients were often seen before audiences of trainees or on videotape, and some systematic methods were used. This is particularly critical, as it pertains to the treatment of children, couples, and families, and because assessment instruments, ethical standards, and advanced technologies were developed to respond to this *glasnost*, or opening of the consulting room door. Second, controlled investigations using the scientific method of generating hypotheses, gathering data, and ruling out sources of variance in order to test the true effects of an intervention took place, primarily within behavior modification and therapy models. This is not surprising because systematic, scientific procedures are inherent in behavioral assessment and treatment, and modifications are continually made that are based on new findings. The following section will discuss one of the earliest and most rigorous series of research studies pertaining to adolescent conduct disorders and families, and it has direct relevance to school counseling.

In 1975, Dr. Gerald Patterson founded the Oregon Social Learning Center (OSLC) and published *A Social Learning Approach: Families with Aggressive Children* (Patterson, Reid, Jones, & Conger, 1975). Since that time, dozens of rigorous studies have been done focusing on the general topics of children and adolescents in schools, conduct orders and delinquency, and the relationship among schools, families, and the community. The following is an example of a research project by the OSLC that is highly relevant for school counselors.

Linking the Interests of Families and Teachers (LIFT) is a research intervention program designed to prevent the development of aggressive and antisocial behavior. Classes from 12 schools (first and fifth grades) located in neighborhoods with a high rate of juvenile crime have been included. All families in the selected grade level were asked to participate. The enrichment school participants participated in the assessment-only phase of the program. The assessment included observations on the playground, peer ratings, teacher ratings, family interviews, parent and child questionnaires, family interaction tasks, and school and court records queries. In addition to the assessment described, the prevention school participants received an intervention designed to prevent problem behaviors from developing or progressing by simultaneously influencing parents, teachers, and children to (1) enhance family interactions, (2) increase prosocial and reduce negative peer interactions, and (3) improve the coordination between home and school. The effectiveness of the intervention is being evaluated through a research design that includes preintervention, postintervention, and yearly follow-up assessments of all participants. In addition, these assessments provide an opportunity to comprehensively examine the factors that support or impede the success of important transitions children and families make as the child begins elementary school and moves into middle school, high school, and young adulthood (Eddy, Mayne, & Reid, 2000).

In reviewing the dimensions of this study, it is hard to imagine a project that would be more comprehensive or useful to anyone involved with schools. Over the 30-year history of the OSLC, studies have demonstrated the positive results that occur through providing prevention and education programs and fostering close collaboration between families and schools. School counselors often serve as a bridge between students, teachers, administrators, and parents, and provide the expertise to foster communication and provide valuable information.

The Oregon studies and others also highlight a key function, and in the author's view, the most critical one a school counselor can play in the family–school interface: a *consultant* and *facilitator* role. More than counselor/therapist or educator, the school counselor is in a unique position to provide a framework and perspective for teachers, parents, and administrators to both prevent and solve problems faced by students. In this role, the key tool for the counselor with a scientific or empirical approach is to assess needs and problems carefully, to generate options, rule out irrelevant variables, and collaborate with others in implementing the most efficient and effective solution. Thus, a student who is referred to a counselor for disruption in the classroom may not benefit from ongoing one-to-one counseling so much as having the various circumstances (times, locations, persons, significant changes, etc.) explored carefully with the teacher, student, and family, so that appropriate interventions can be made. The successful approach may be as simple as recommending that the teacher ignore disruptive comments and reward constructive ones, or moving the student to another section. The OSLC has also conducted investigations into delinquency, substance, abuse, and violence. Brigman, Mullis, Webb, and White (2005) emphasized that the role of consultant for school counselors is the most effective one they can serve and pointed out that it reaches the greatest number of students and creates a more responsive school environment.

Another significant area that closely links theory, research, and practice is the *scholarship of engagement,* a concept that incorporates collaboration between academic and community

professionals and consumers of services. The process of top-down, ivory-tower-generated research becomes reversed, and issues to be addressed originate in the real needs of those who are to be studied.

One example is a study in Australia (Dancer & Fiebig, 2001).

> Using a sample of several hundred students enrolled in the Faculty of Economics at the University of Sydney, we modeled progression in the first-year econometrics course. Our primary interest was the identification of "students at risk." This interest highlighted the need to distinguish between students who dropped the course and those who completed, but ultimately failed, the course. The models allowed identification and quantification of the factors that were most important in determining student progression and thus made them a potentially useful aid in educational decision making. There was some evidence that students who discontinued and those who failed have different characteristics; however, there was very clear evidence that these two groups do have different characteristics from the group of students who passed the course. It is vital to identify those "students at risk" early in the semester, and these results help this process. (p. 21)

The key element in this practical research study was to involve the community in determining the problem to be studied, generating hypotheses, gathering data, analyzing results, and developing solutions—a fundamental "bottom-up" approach.

Another multisite research project, funded by the federal government, found substantial benefits from family involvement in adolescent substance abuse treatment (Liddle, 1991). Other widely implemented projects with extensive research foundations have demonstrated the benefits of prevention and intervention programs for at-risk children, including a large program implemented in Australia by Mark Dadds (2002) and another used throughout the United States for adolescents and their families by Thomas Sexton and James Alexander (2002). Others of interest to school counselors include studies on the relationship of family environment and marital quality to child adjustment (Jouriles & Farris, 1992; Miller, 2002), parent management training (Kazdin, 1997), and the *Steps to Respect* Program, a large-scale study in elementary schools in the Pacific Northwest designed to teach respect and avoid bullying (Frey, 2005).

Pragmatic research findings such as those mentioned can often demonstrate cause-and-effect relationships in common situations and provide a framework for counselors to explore the specifics of a given context. Thus, school counselors are encouraged to become conversant with relevant research and intervention programs that have been proven effective and to serve in a consultative role, providing prevention and education programs; counseling students; serving as a bridge between students, administrators, and parents; and making informed referrals to external services.

Practice

Let us now clearly define what we mean by involving families in schools and closely examine what is done now. The key concept is for parents and other family members, including anyone with significant responsibility for caretaking or providing important services to students, to be in a *partnership* with teachers, administrators, and counselors so that there will be a seamless integration with the school, home, and community. This may seem like an unattainable ideal, but it is the ultimate objective for school personnel who attempt to solve common problems and to serve students' needs. Participating in parent–teacher organizations, volunteering, fund-raising, serving on school and community boards, chaperoning, and coaching have all provided opportunities for parents and other community members to be actively involved in the life of the school. In addition to these types of traditional parent involvement activities, school counselors can provide information to parents and the community on the services they provide, such as academic, career, and personal counseling and education and support on peer relationships, coping strategies, social skills, communication, problem solving, conflict resolution, substance abuse, and diversity issues (American School Counselor Association [ASCA], 1999). It is essential for counselors to establish clear lines of communication with parents and be an effective liaison with officials and specialists in the community to obtain input and support on these and other important activities.

Counselors who will readily agree with this concept may point out the difficulty of involving family and community members due to scheduling, distance, disinterest, lack of staff, and disorganization. While these are realistic concerns and not all students will have family members who participate, an *ethic of partnership* that pervades a school from top to bottom can elicit involvement and create an atmosphere that is contagious and draws people to take part in vital activities.

In fact, the opposite of partnership often occurs regarding family involvement. Aside from traditional "back-to-school night," occasional newsletters, and crisis situations, the school counselor can be alone when it comes to involving parents in the school lives of their children.

When policies do not require parent participation and resources are not allocated, counselors are frequently left carrying the ball when a student is identified with a problem. Difficult behaviors such as disruption, withdrawal, lateness or truancy, and poor academic performance that are left solely on the counselor's plate can exacerbate and become intractable if parents do not feel part of the program, and administrators and teachers do not "own" a share of the problem and collaborate on developing solutions.

School counselors cannot do it alone. School boards, parent organizations, and principals who develop expectations and meaningful activities for families to share in the life of the school as a condition of admission and retention can facilitate regular contact between teachers, counselors, and other staff. Whether written, verbal, or electronic, information provided on a regular basis to parents keeps them "in the loop" and diminishes anxiety when student problems arise. As innovative programs or partnerships with nonprofit or business organizations are publicized, a sense of pride develops that strengthens parents' sense of partnership with the school. The underlying concept is one of positively reinforcing parents and increasing awareness of student and school achievements, rather than waiting for problems to arise. Although they may be well beyond their school years, parents, too, feel a tinge of apprehension when teachers, principals, or counselors call if contacts occur only around problems, and an avoidance response can inadvertently develop and further separate families from their children's lives in school.

Dos and Do Nots of Effective and Efficient Family Involvement

School boards, administrators, and teachers are urged to

- develop policies that provide encouragement and procedures for community partnerships between schools and businesses, social agencies, health facilities, law enforcement, and other community groups;
- provide incentives for parents to become involved on an ongoing basis from the time a student is admitted to school through graduation; and
- frequently publicize successful collaboration, especially examples of preventing potential problems and of social and academic success.

The concept of partnership, based on positive reinforcement and awareness, leads to some clear practices for counselors, supported by their schools, to facilitate parent involvement. In the earlier section on the genesis of the family therapy movement, a rationale was provided for involving *entire* families, or as many critical members as possible, in education, prevention, and counseling. Thus, school counselors are in a unique role to advocate for school–community partnerships, develop them, and take advantage of opportunities to draw parents into their children's activities: *as many as possible and as often as possible*. Specifically, in order to facilitate and strengthen parent involvement, school counselors can

- advocate and develop procedures and activities to involve families;
- provide useful, relevant information to parents on a regular basis through newsletters, workshops, Web sites, and e-mail;
- give parents periodic updates on social, emotional, vocational, and other relevant progress of their children;
- when critical situations arise, give background and other relevant information and arrange for key family members and other caregivers and professionals to meet together as appropriate, scheduling meetings—whenever possible—near worksites and at home; and
- assess problem situations systematically and provide options in order to reach collaborative, comprehensive solutions.

Administrators, board members, teachers, and parents are urged *not* to

- contact parents and invite their involvement only when funds are needed or problems arise;
- refer to counselors and utilize their services only when problems arise with students, and fail to collaborate in the assessment and treatment of problems; and
- expect school counselors to deal with complex family, social, and psychological issues that require specialized or ongoing treatment and referral.

School counselors are strongly encouraged *not* to

- operate as though they were in private practice, seeing students in ongoing, individual sessions without involving, families, teachers, administrators, and the community, as appropriate, and
- ignore the boundaries of their competence, and fail to refer to specialists as needed.

Counselors are required to serve many masters: teachers, administrators, parents, students, and the community. Therefore, they need to define their roles clearly and uphold the ethical standards of their profession. For a discussion of the ethics of school counseling, please refer to "Ethical School Counseling: Managing a Balancing Act" (T. E. Patterson, 1998).

Case Example and Implications for Multicultural Counseling

A highly visible public relations campaign says it best: *Si usted puede llegar aqui, se puede visitar la escuela de sus niños: participe, collabore!* (If you can arrive here, you can visit your children's school: participate, collaborate!) In that spirit, and to illustrate the concept of partnership, please consider the following example.

Armando and Estella Rivas are parents in their late 30s and have two boys, Esteban, age 10, and Hector, age 9, and one girl, Leida, age 7, in Buena Vista Elementary School in a major city. Both parents work in demanding jobs (Armando works 6 P.M. to 2 A.M. and Estella works 8 A.M. to 4 P.M.) and have been in the United States (they are from Nicaragua) for 12 years. Estella's mother and younger sister live with them and assist with child care and provide small incomes, although finances are still tight. Esteban is a high achiever and Leida is quiet, yet she has some friends and does well academically. Hector has a learning disorder (dyslexia) and a short attention span, and he has had to repeat his current grade (grade three) due to academic and behavioral difficulties. The parents have been interested in his progress and have responded to phone calls and attended teacher conferences, yet Hector's problems have been ongoing.

In October of Hector's second year in the third grade, Mr. Yi, his teacher, asked the school counselor, Ms. Jackson, to see Hector due to his difficulties with paying attention and completing his assignments, saying that his behavior was distracting to other students in class. Ms. Jackson scheduled a conference with Mr. Yi and obtained detailed information about Hector's past and present classroom activities (Mr. Yi was his teacher the previous year also), and requested an opportunity to observe Hector in class. She also obtained Hector's cumulative school folder and included significant academic and behavioral information in the file she had started on Hector. Ms. Jackson then contacted Mr. and Mrs. Rivas and, learning of their work schedules, arranged to meet them in their home between their respective shifts (at 4:30 P.M.) to discuss Hector's situation. She discovered that the parents experienced some of the same difficulties with Hector at home and in outside social situations, but they did not consider him to be *malcriado* (bad intentioned), but rather *dificil* (difficult). Their pediatrician had suggested that Hector was hyperactive at age 4, but they did not want him to be on medication.

Ms. Jackson wondered whether his attention span and task completion varied according to where he was, the task itself, or whom he was with. She noted in his school folder that similar problems had been observed since kindergarten, although when he was with one other person or was working on an art project (drawing or painting), he could sit for 30 minutes or more, was not disruptive, and could finish his project with some prompting. Rather than seeing Hector in individual counseling, she asked the parents if they could arrange a frequent time and place for Hector to draw in a quiet location with a sibling or friend. She suggested to Mr. Yi that he allow Hector to work with a classmate of his own choosing in a corner of his large classroom once each morning and afternoon, beginning with drawing and then shifting to the class assignment. Fortunately, Mr. Yi had a teaching assistant and agreed to try this approach, and after one week, he reported that Hector's behavior and attention were fine during the special periods and somewhat improved at other times also.

Ms. Jackson then contacted the school psychologist and requested that Hector be tested and that an individualized education plan (IEP) be developed. The testing confirmed the dyslexia as moderate, and the attention deficit appeared to depend upon the specific task and context. Weekly sessions with an educational specialist for Hector's dyslexia were arranged at a community center near his home, and Ms. Jackson found that a group had been formed there to assist adults and English as a Second Language (ESL) children who also had reading difficulties. Unfortunately, this group met only in the evenings, and Ms. Jackson successfully petitioned for a group to be formed to meet at the Buena Vista School on alternate Saturday afternoons. Hector attended the group there with children with other learning problems and was given special attention, and the parents were provided with information and the support of other parents. As a result, Armando and Estella also made it a point to arrange time off from work to attend parent teacher activities and other activities at the school because they saw the direct benefits of being actively involved in order to improve Hector's behavior and education.

It is notable that instead of automatically seeing Hector in individual counseling for the referred problem, Ms. Jackson took a broader approach and explored the history and current context of his situation. She did not view his inattention or disruptive behavior as an indication of either an emotional or a family problem, but rather as a specific deficit that could be addressed with environmental changes in the classroom, with specialized services, and with family and community support. She also went beyond the context of the school itself in arranging home visits and engaging the parents and community, which undoubtedly resulted in some lasting changes that benefited other parents and students. She embodied the concept of partnership, and she used a basic systems approach in creating a comprehensive solution to the referred problem. Ms. Jackson was also attuned to the cultural and specific context of this family, and she successfully discovered and expanded available resources. School counselors are urged to consider this model, which initially requires a period of assessment

and outreach and ultimately necessitates less intensive individual effort and responsibility and results in longer term solutions.

Although this case involved a Latin American family, its applications are widespread. If we consider the terms *culture* and *diversity* to encompass every type of difference, such as personality style, gender, sexual orientation, race, ethnicity, religion, socioeconomic status, geography, occupation, immigration, and disability, the first thing that becomes obvious is that just as group membership may be crucial to one's identity, such affiliation does not solely define an individual. Nor is it the purpose of this chapter to specify cultural differences, as illustrated by many excellent texts such as one by D. W. Sue and D. Sue (1999). It is also incorrect to assume that "minorities" are different from the norm, as the very definition of a "dominant culture" is constantly shifting, in both metropolitan and rural areas. Examples of differences that can intersect all groups are emphasis on individual versus community goals, loyalty to family, adherence to rituals, organized religion, career and education, and other dimensions. Thus, we may find a Native American who was raised in urban North Dakota by college-educated parents to have more in common with an Irish American from Chicago than with a Native American raised on a reservation in South Florida, though the Native Americans might adhere to the tradition of revering one's ancestors to a similar degree. This value might be shared by an African American from Louisiana who was raised in a Creole folklore tradition. The element essential for counselors to be *culturally competent* is to become knowledgeable about diversity as much as possible, while assessing the aspects of each individual that make her or him think, feel, and act in unique ways. Thus, awareness and skill in dealing with diversity is critical, and it is equally important to avoid stereotyping on the basis of group identification.

Future Directions

This chapter has reviewed the foundations and the impact of family involvement in schools and the importance of bringing community resources to bear in devising solutions. It has also outlined the models and practices in the mental health field to address family participation in assessment and intervention, particularly from a systems perspective. Practical, relevant research supports the roles of parents, nuclear and extended family, and other community individuals and groups in school activities. Numerous examples exist of successful collaboration, or partnership, which prevents and resolves problems, and enhances the quality of students' lives in schools, but much remains to be done.

The *scholarship of engagement* concept offers some of the brightest promise for school counselors to engage in partnerships with others in a relevant context to improve services to students while contributing scholarly information to the field. Projects can range from engaging students interested in careers in environmental management by studying pollution levels in disadvantaged communities to soliciting feedback from parents about their expectations of how they might be assisted most effectively when their children experience behavior problems. Teachers might be involved in exploring and testing alternative methods for counselors to observe and obtain systematic feedback on classroom and other school behaviors, and administrators can be surveyed and interviewed regarding their perceptions of the effectiveness of referrals made to school counselors and how to generate community resources in solving school-based problems. Alternatively, the experiences of students could be used as a basis for applying existing research to address bullying in middle schools. In similar fashion, the ideas of secretaries, custodians, teacher aides, and parent volunteers might be solicited for their observations and suggestions regarding student interactions in hallways, playgrounds, and in the cafeteria as part of developing a comprehensive model of assessment and intervention (for further information on this concept, see Boyer, 1996, and http://www.scholarshipofengagement.org).

In practice, counselors are encouraged to consider the example described above of Ms. Jackson, the school counselor who did not view Hector's difficulties in terms of an individual conduct disorder or family dysfunction, but rather as an issue to be systematically evaluated by engaging key individuals and groups in order to devise a comprehensive solution. Perhaps counselors who immediately take it upon themselves to address referrals from teachers and administrators only through private, individual sessions either do not feel that others are willing to be involved or are trained in a model of counseling that views problems only as pathologically based, or residing within the person.

Without debating the merits of different theories, it is apparent to nearly everyone that too many issues arise and not enough time or counselors exist to address problems solely in private sessions and that greater, more enduring outcomes can be achieved with a collaborative approach. We are not, however, encouraging counselors to be social workers, and we urge what one author has stated: "Solve school problems at school and home problems at home" (Palmatier, 1998, p. 442). Achieving the proper balance requires counselors to have a clear definition of their roles, and to serve as bridges between the school and the home and community. Thus, counselors are encouraged to (1) collaborate with teachers and administrators in developing effective referral, assessment, and intervention policies and procedures to address student issues; (2) assess presenting issues systematically and thoroughly when they are referred; (3) obtain as many records and reports relating

to the problem as possible; (4) involve relevant specialists in obtaining a detailed assessment; and (5) involve key individuals within the school and in the community in generating alternative solutions and involve them in the implementation and evaluation of the plan.

The role of trainers and educators of school counselors emerges directly from the systemic model, the concept of partnership, the scholarship of engagement, and the examples described above. Instead of teaching only theory (especially an individual, problem-based one), training should involve a comprehensive model, include opportunities in the curriculum for students to explore real problems faced in the schools, and provide an empirical, student–family–community based perspective. Besides taking on cases referred by counselor–mentors, counseling trainees can then evaluate the dimensions of referred problems, talk with those involved, and produce a practical term paper to be shared with personnel in the school. Trainees should be expected to meet with families in their homes and become knowledgeable about community resources. Collaboration with training faculty can generate grants to fund such projects, based on the scholarship of engagement and coordinated with programs such as *Teach for America*. With this model, counselors can be initiated into a partnership that actively engages them in academic and practical approaches and prepares them for effective careers that will immediately benefit schools, students, families, and communities.

The significant understanding that has emerged from the study and experiences with diversity needs to be expanded in working with students, families, and communities. There may be no better context for examining cultural values and developing new approaches than in the complex environments of today's schools. The diversity present in our schools presents opportunities for counselors to collaborate and consult not only on promoting equality, but also in teaching invaluable lessons for students to use throughout their lives.

In summary, what should be the role and objectives of school counseling? Certainly, all of the goals and tasks detailed in ASCA (1999) guidelines should be included. While individual counseling is one appropriate role for counselors, state guidelines defining the scope of practice of school counseling clearly do not specify that role to be *psychotherapy* or any type of in-depth, long-term private sessions. Experienced school counselors, teachers, and administrators will readily acknowledge that this is not possible or expected in most situations, nor do students or parents understand or give informed consent to such a process. They do expect needs and problems to be anticipated, prevented, and addressed directly in the most efficient and effective manner. The school counselor is therefore in a central position to be an *evaluator* and *facilitator,* rather than the sole agent to address students' individual problems. Counselors' expertise is based on their ability to understand, from a systems perspective, the complex ways in which situations impacting students develop and on their skill in collaborating with others to craft efficient, effective solutions. While individual, family, or group counseling may be one element in that process, other methods such as careful assessment, outreach, and collaboration can be more comprehensive and enduring. This model is offered as a universal one for school counseling professionals to consider, recognizing the vast experience, accumulated wisdom, and continuing crucial role that school counselors play in the lives of students.

XXX
CRISIS MANAGEMENT IN THE SCHOOLS

MICHELLE L. MURPHY
University of North Florida

Introduction

As an organized body of knowledge, skills, and practice, the field of crisis intervention is relatively young. However, it has experienced heightened momentum in the last decade because of the widespread media coverage of growing numbers of school tragedies and the resulting ripple effect felt in school communities throughout the country. Nationwide, there is increased awareness of the need for effective crisis prevention and intervention in schools (Allen, Jerome, et al., 2002; Brock, 1998; Dwyer, Osher, & Hoffman, 2000; Klicker, 2000; Malley, Kush, & Bogo, 1994; Poland & McCormick, 2000; Wittmer, 2000). Crises of varying types and degrees can and do happen in all types of school communities every day, and school personnel and students are exposed to an increasing number of personal crises and traumatic events. According to Stephens (1994), schools face two types of crises: those they are currently dealing with and those about to happen. Thus, even with the most diligent prevention efforts, it is highly likely that a school counselor, at some point, will be called upon to provide crisis intervention services and/or be involved in larger scale crisis management efforts.

Crisis intervention is typically defined as a short-term, goal-directed helping process focused on resolution of an immediate problem and stabilization of resulting emotional conflicts. Prompt intervention should be geared toward reestablishing emotional and behavioral stability, providing support, and facilitating the needs of those most closely impacted by the crisis (Klicker, 2000). School counselors have the opportunity to become the response initiator, trainer, service provider, and advisor for crisis situations in the schools. However, their current roles must be expanded to include developing, training, and implementing strategies and support services designed to address crises that impact the school community.

Although school counselors have knowledge of a broad range of adolescent developmental issues, they need to acquire specific skills in developing and implementing prevention programs as well as the competence to intervene and respond to various crisis scenarios. Comprehensive crisis management involves efforts to prevent crises, such as school violence and suicide, as well as postvention efforts designed to minimize the impact of traumatic events, such as homicide, student deaths, and natural disasters, on the school community. However, effective prevention and intervention become unrealistic expectations when school counselors are not competent, capable, or adequately prepared to understand and handle a wide array of crisis situations. Given the increasing number and variety of crises impacting schools, a thorough understanding of the crisis intervention process and training in crisis intervention skills, with a specific emphasis on suicide intervention, are essential for school counselors.

This chapter establishes the scope and significance of crises in the schools and provides a rationale for the importance of school-based intervention in crisis situations, including a discussion of prevention efforts, crisis training activities, and crisis response procedures. I present an overview of the nature of crises, crisis theory, and the field of crisis intervention, with particular emphasis on crisis intervention in the schools. A review of the current literature in the field and a framework to guide school counselors toward effective prevention, preparation, intervention, and postvention efforts is provided. The benefits of developing a crisis intervention team, obstacles that can impede the development and implementation of the crisis intervention plan, and strategies for minimizing identified obstacles are also discussed.

Scope of the Problem

Every day in America, on average, 15 children are killed by firearms, 13 are victims of homicide, and 6 commit suicide. According to the *Indicators of School Crime and Safety 2000*, during the 1997–1998 school year, there were 60 violent deaths at school, including 47 homicides, 12 suicides, and 1 student killed by a police officer in the line of duty (National School Safety Center, 2001). However, widely publicized, school-based crises are still relatively rare compared with the rising incidences of depression, suicide, and physical, sexual, and psychological abuse/neglect, which are frequent causes of crises among children and adolescents. Schools are also faced with deaths in the school community, accidents, natural disasters, and terrorism concerns, all of which require crisis intervention in the schools on a much more frequent basis. According to Pitcher and Poland (1992), these types of traumatic stress, which result from unpredictable and uncontrollable losses, are the most common crises experienced in schools. These crisis situations expose students to "threat, loss, and traumatic stimulus" and undermine their "security and sense of power" (Johnson, 2000, p. 3).

Suicide is the second leading cause of death for adolescents and, thus, an integral part of any discussion of school crises (Hayden & Lauer, 2000; King, Price, Telljohann, & Wahl, 1999, 2000; Poland & McCormick, 1999; Popenhagen & Qualley, 1998). Gallup polls have indicated that 60% of teens reported personally knowing someone who had attempted and 15% knew someone who had actually completed suicide (Cohen & Fish, 1993). Students' lives are often grievously impacted by those who attempt or complete suicide, and adjustment after a completed suicide often impacts the entire school community because of the atypical nature of the death and the social stigma involved (Clark, 2002).

Issues related to overall school climate, such as bullying, alienation, and harassment, can influence the likelihood of school crises. For instance, Petersen and Straub (1992) cited the following environmental factors in schools that increase the risk of suicide or violence: transitions and restrictions imposed by "the system," lack of specialized programs and services, a social climate with strong cliques and factions, and the alienation and rejection of certain types and/or groups of students. Bullying, the most common form of violence occurring in schools, is continuing to increase. Nearly 30% of U.S. students report being involved in bullying as either a target or a perpetrator, and more than one in three students said they did not feel safe at school (National School Safety Center, 2001). Tolerance of bullying behaviors creates a hostile school climate that increases the likelihood of crisis (Olweus, Limber, & Mihalic, 1999). According to Hazler and Carney (2000), violence can be viewed along a continuum, with peer-on-peer types of abuse, such as teasing, harassment, and bullying, at the lower end and school assaults, murders, and suicides at the higher end. In fact, a history of bullying, persecution, and threats has been associated with 66% of the school shooting incidents (Vossekuil, Reddy, & Fein, 2000). These data also indicate that children who are bullied report more loneliness and social isolation, while those who are doing the bullying were more likely to perform poorly academically and engage in substance abuse. All of these behaviors and characteristics are considered risk factors that would place both targets and perpetrators at greater risk for crisis.

Furthermore, the impact of more "typical" developmental crises is multiplied and magnified by the increasingly complex issues facing today's school-aged youth and by declining family and community support systems. The influence of societal problems on adolescents is reflected in dramatic increases in substance abuse, suicide, child abuse, teen pregnancy, truancy, school dropout, and random acts of violence (Pitcher & Poland, 1992; Wittmer, 2000). According to Caplan (1964), crises challenge coping resources, jeopardize an individual's sense of emotional balance and stability, create psychological distress, and cause individuals to feel trapped (i.e., unable to escape or effectively deal with the problem at hand). Given the inevitability of crisis and its damaging impact, it is clear that crisis intervention in schools is a necessary mechanism for helping students deal with these increasingly common threats to their growth and well-being.

The Nature of Crisis

The Chinese symbol for crisis is a combination of two characters that represent both danger and opportunity. The *Encarta World English Dictionary* (2002) defined *crisis* as

> A time when something very important for the future happens or is decided [and] a situation or period in which things are very uncertain, difficult, or painful, especially a time when action must be taken to avoid complete disaster or breakdown.

A crisis entails the unexpected and usually involves change and loss (Erickson, 1963; Hendricks & Thomas, 2002; Lindemann, 1944). A typical crisis consists of the following five components: a hazardous event, a vulnerable state, a precipitating factor, an active response state, and the resolution (Roberts, 1990).

Crisis situations occur periodically throughout the life span, and they may be triggered by either a single catastrophic event or the cumulative effect of successive stressors. Although once viewed as pathological, crisis reactions

are now recognized as normal responses to abnormal situations. The following characteristics of crisis situations have been identified: (1) the presence of both danger and opportunity, (2) complicated symptomatology and ineffability, (3) seeds of growth and change, (4) the absence of panaceas or quick fixes, (5) necessity of choice and action, (6) time-limited acuteness, (7) universality and idiosyncrasy, and (8) an obstruction of goals and loss of control (Gilliland & James, 1997; Romano, 1990, as cited in Hendricks & Thomas, 2002).

The emotional intensity of a crisis reaction may range from severe pain to numbness but is typically characterized by some degree of confusion, discomfort, anxiety, vulnerability, disorganization, helplessness, and/or disequilibrium. The crisis state produces distress that is primarily associated with an overwhelming precipitating event and an inability to cope with or adapt to the resulting circumstances. Personality characteristics of individuals in crisis include a lowered span of attention, an inability to discriminate between stimuli, introspection, uncontrolled emotional responses, impulsivity, limited perspective, and subtle and/or overt help-seeking behaviors (Hendricks & Thomas, 2002).

Crisis is a subjective reaction to a stressful life experience; it is an individual's perception of and reaction to an event that shapes a crisis, not the situation itself (Roberts, 1990). In other words, a person's feelings of shock and distress *concerning* the disruption will determine the crisis reaction, not the disruption itself. Therefore, an individual's perceptions, skills, experiences, and abilities cannot be viewed in isolation (Palmatier, 1998). Crisis is essentially a relational phenomenon and cannot be understood, prevented, or resolved without attending to the contexts and structures surrounding a distressed individual. According to Hendricks and Thomas (2002), "[T]he *interpersonal* experience of the individual in response to the *event* that in some way involves others in the *interpersonal* environment is the foundation for understanding the dynamics of crisis formation" (p. 7).

Expectations and assumptions for handling traumatic situations are shaped by an individual's worldview. For example, values associated with culture, gender, religion, and social roles influence the interpretation of and reaction to crises and may have implications for coping strategies, communication styles, emotional expression, and help-seeking behaviors. Counselors must be aware of how their own values and assumptions about crisis situations influence their work. For instance, cultural norms prescribing emotional restraint for Asians or expression of grief for African Americans may be viewed as maladaptive when viewed through a Eurocentric lens. It is important to remember that crisis is a normal reaction to an abnormal event; each individual's unique, personal experience of the crisis should be validated and accepted without imposing one's own values on how the crisis response should be manifested or effectively resolved.

Crisis is an intrinsic part of life, and despite efforts aimed at prevention, crises will continue to occur. Timely, efficient intervention frequently leads to the positive resolution of a crisis and minimizes the likelihood of future physical or emotional deterioration. According to Terr (1992), "[I]f a traumatic response does not have the chance to become entrenched, it will become only a small scar on a very large life" (p. 77). Increased awareness and understanding of the nature and impact of crisis as well as comprehensive intervention strategies increase the likelihood that individuals will emerge through a crisis stronger and more enriched, as opposed to hopeless and defeated. Well-resolved crises provide the opportunity for the development of improved coping strategies and increase an individual's resistance to the impact of future stressors. Thus, within each crisis lies the opportunity for growth.

School Crises

Schools are one of the major socializing institutions affecting children's lives and are therefore the context within which they experience frequent crises of varying degrees and impact. Within this context, counselors and educators have the opportunity and responsibility to teach students how to effectively resolve crises, cope with the associated and causal factors, and develop an increased sense of resiliency. A school crisis may be defined as an incident occurring either at school or in the community that negatively impacts students, staff, and/or other members of the school community (Trump, 2000).

The simplest criterion for an incident to be considered a crisis is an implied threat to the health, safety, or welfare of students. According to Johnson (2000), a school crisis "brings chaos" that "undermines the safety and stability of the entire school" (p. 18). Similarly, situations that create, or have the potential to create, a disruption of the educational process or normal school operations may be considered crises. Implications for school crisis intervention are particularly significant because of the intensity and frequency of both developmental and situational crises experienced by school-aged children and the unique social dynamics, capable of either alleviating or exacerbating a crisis, of school communities.

Situational school crises typically fall into one of the following three categories: (1) purposeful, human-caused disasters, such as violent crimes, shootings, bombings, hostage taking, teacher victimization, assault, suicide, or murder; (2) accidental disasters, such as transportation accidents, gas leaks, chemical spills, fires, or faulty equipment; and (3) natural disasters, such as hurricanes, torna-

does, floods, or earthquakes (Hill & Hill, 1994). However, given that crises are shaped by individual perceptions, it is important to realize that developmental crises, such as social isolation or interpersonal conflict (although less consensually traumatic) can evoke feelings that create a crisis state solely for the individual experiencing them.

Developmental crisis refers to the stress and anxiety associated with transitioning from one developmental stage to another and often relates to meeting the demands and resolving the tensions of the new stage. For example, the transition from middle to high school comes at a time when many students are worrying about their values and personal identities. This transition period frequently leads to crises when personal decisions cause conflict between family and/or cultural values and the values of their peers or social groups. The frequency, intensity, and duration of developmental crises vary depending on the individual's combination of personal, social, and environmental resources.

According to Johnson, Casey, Ertl, Everly, and Mitchell (1999), crises that are ignored or resolved ineffectively create posttraumatic stress responses that compromise the achievement of the goals of education in the following ways: (1) creating adverse reactions that affect learning, (2) reducing the ability to concentrate, (3) disrupting attention, (4) interfering with socialization, (5) causing difficulties in memory retention and retrieval, (6) becoming preoccupied with the traumatic experience, (7) regressing to earlier levels of coping, and (8) heightening physiological arousal and startle reflexes. Johnson et al. suggested that school personnel often misinterpret many of these problems and associated crisis-related behaviors as discipline issues, and thus, students are frequently punished as opposed to receiving appropriate intervention services.

The experience and resolution of crises in the schools is influenced by the unique dynamic of each school community. Factors, such as preexisting school climate, administrative support (or lack thereof), geographic location, facilities, and surrounding community resources, combine to enhance or inhibit crisis management. The location of a school in a particular urban, suburban, or rural area has implications for access to multiple resources during a crisis as well as for the amount of ripple effect that is felt throughout the surrounding community. For instance, a completed suicide in a small, rural town with strong religious ties may impact the community differently than if the same event were to occur in a large urban school, where violence is a more frequent occurrence. Similarly, for schools in areas where services are limited, proactive planning efforts should establish links with neighboring communities and develop networks for obtaining necessary support and resources, as needed. School counselors must know their schools and communities in order to effectively tailor their intervention efforts to respond to the specific needs.

Crisis in the context of schools is complex because of the unique features of a school's social structure and the shared sense of community. An efficiently managed crisis can provide valuable opportunities to model care and concern and can be used to unite students and staff, forming a sense of understanding, trust, and cohesiveness. Minimizing or denying the effects of crisis sends the message that an individual's distress is insignificant and may suggest that the crisis was so overwhelming that school staff was not able to deal with it directly. According to Hendricks and Thomas (2002), "[A] common crisis-producing event is the feeling that 'I have failed to cope adequately'" (p. 5). In the midst of a crisis, feelings of failure, isolation, and guilt increase the likelihood that another crisis will occur. Schools should be prepared to provide students with a sense of hope, stability, security, and optimism. The sense of community that comes from sharing an emotionally charged experience will not be realized if schools choose to maintain a "business as usual" approach to crisis situations or personal tragedies.

Suicide and aggression. Furlong, Morrison, and Pavelski (2000) suggested more implications for prevention and intervention become apparent when the definition of school crisis is broadened to include a continuum of harmful behaviors encompassing social and psychological harm. Furthermore, the scope of prevention and intervention activities should be expanded to include a focus on both outwardly directed acts and inwardly directed acts of aggression. There is support for the idea that maladaptive behaviors often occur in crisis situations in which isolated teens see no other option (Beautrais, Joyce, & Mulder, 1999; Bolton, 1993; Hazler & Carney, 2000; Kalafat, 1993). That is, adolescents often perceive that there are no solutions to their problems, and they turn to suicide or violence as the means to reduce their pain and torment or to cope with their out-of-control emotions. Violence toward oneself or others is frequently used by youth to release pent up feelings of anger or frustration. Statistics on adolescent suicide alone "require the school practitioner to develop skills to intervene with suicidal students and to develop primary prevention strategies for the school" (Davis, Sandoval, & Wilson, 1993, p. 265).

Suicide and aggression are inherent risks associated with crisis because of the hopelessness and despair that often accompany the crisis response. As problem-solving skills and coping abilities become overwhelmed, a crisis gains momentum, personality fragmentation occurs, and the crisis victim/survivor moves toward specific patterns of maladaptive behavior (Hendricks & Thomas, 2002). Researchers have suggested that poor impulse control may be the common link that influences the co-occurrence of these maladaptive behaviors (Simon & Crosby, 2000).

Specifically, a link has been found among the subjective experience of problem irresolvability, the sense of loss of control, and suicidal behavior (Jacobs, as cited in Orbach, Mikulincer, Blumenson, Mester, & Stein, 1999), all of which are essential issues to be addressed in any comprehensive crisis intervention program. An accumulation of negative life events and experiences in conjunction with inadequate problem-solving skills has a major impact on the frequency and intensity of anger experienced at school (Fryxell & Smith, 2000) and contributes to feelings of hopelessness and suicidal ideation (Ayyash-Abdo, 2002; Bolton, 1993; Simonds, McMahon, & Armstrong, 1991). Both suicide and aggressive behavior represent ineffective means of coping or resolving crises.

According to Studer (2000), "[B]ecause individuals experiencing a crisis are often difficult to be around (Aguilera, 1998), the real or imagined distance created between the suicidal individual and significant others may result in greater isolation, loneliness, and loss of a support system" (p. 270). Jobes (2000) asserted, "Suicidality is essentially a relational phenomenon. Specifically, the presence and/or absence of certain key relationships can paradoxically be both suicide causing and suicide preventive" (p. 8). For example, repeated disruptions of family life, such as parental discord, separation, caretaker changes, and physical or sexual abuse, have been linked to suicidal behavior, and 52% of adolescent suicide attempters revealed having problems with their parents (Studer). Thus, the school counselor's overall knowledge regarding adolescent suicide may directly determine the likelihood that at-risk students will successfully be identified and given the proper help (King et al., 2000). These findings have implications for the importance of school counselors' being able to identify, build rapport with, and convey empathy to students in crisis quickly and efficiently.

Risk factors. Using the categories developed by Hazler and Carney (2000), factors which would make a student more likely to experience a crisis and/or contribute to difficulties in the resolution of crises can be classified as follows:

- *Biological risk factors:* developmental transition issues, rapid physical and psychological changes, and dramatic hormonal fluctuations
- *Psychological risk factors:* depression, helplessness, hopelessness, low self-esteem, loss of motivation, anxiety, irritability, feelings of personal futility concerning the future, and hostility
- *Environmental risk factors:* lacking social competence, peer acceptance, family support, and meaningful relationships with others; academic or legal difficulties; high levels of chronic stress; and physical, emotional, or sexual abuse
- *Cognitive risk factors*: negative self-attribution, idealistic thinking, increased egocentrism, rigid or inflexible thinking, poor problem-solving skills, a negative or hopeless outlook, and an inability to foresee future consequences

All of the factors just mentioned are considered risk factors for youth suicide and violence. However, the strongest risk factors for suicide in youth are depression, alcohol or other drug use disorder, and aggressive or disruptive behaviors. It should be noted that any factors that increase the likelihood of rejection or peer alienation would also place students at higher risk for maladaptive coping. For instance, gay, lesbian, bisexual, and questioning youth face considerable obstacles both at home and school, and they often experience bullying, social isolation, and the loss of family support. Counselors should take steps to identify students who are more vulnerable to risk factors and attend closely to warning signs of potential crises so that interventions targeting these students will be timely and effective.

Females are 3 times more likely than males to attempt suicide, males are 5 times more likely than females to complete suicide, and gays/lesbians are 3 times more likely than heterosexual youth to engage in suicidal behavior (King et al., 2000). Caucasian adolescent males complete suicide at much higher rates than any other ethnic group, so extra efforts should be made to identify vulnerable students and involve them in early intervention efforts. Similarly, because Native Americans and Alaskan Natives have the highest adolescent suicide rates rate of any ethnic group, school personnel and parents should be aware of early warning signs and take efforts to prevent the development of at-risk behaviors (Capuzzi & Gross, 2004). According to Metha, Weber, and Webb (1998, as cited in Capuzzi & Gross, 2004), suicide rates for both Hispanic-American and Asian American adolescents continue to be lower than those for Native-American and African American youth, even though the period between 1980 and 1994 indicated higher rates than previously recorded. Similarly, despite significant increases in African American suicide rates during the same time, overall patterns in the data indicate that the suicide rate for African American adolescents remains lower than that of Caucasian adolescents. Some models indicate that cultural pressures associated with oppression may help to create protective factors that lower the risk of suicide.

Theory

The Origins of Crisis Intervention

Crisis intervention is a process by which trained crisis workers identify, assess, and intervene with distressed individuals to restore balance and reduce the negative effects of

crisis in their lives. It involves an immediate response to and resolution of an urgent problem, focusing particularly on stabilizing emotional functioning and minimizing the long-term ramifications of the crisis (Hoff & Adamowski, 1998). Intervention becomes necessary when individuals have exhausted their skills for coping and feel hopeless and overwhelmed by their current situation. In 1906, the establishment of the nation's first suicide prevention center, in New York City, confirmed that effectively resolving a crisis frequently requires the provision of support and resources external to the individual experiencing the crisis (Brown, 2002; Roberts, 1990). According to Hoff and Adamowski, "A truism about the human condition is the community's recognition that most individual members cannot manage stressful or traumatic life events alone if they are to avoid potential pathologies or fatal outcomes" (p. 5).

According to Hendricks and Thomas (2002), early research, conducted without the benefit of the umbrella term "crisis intervention," focused on diverse and seemingly unrelated areas, such as "mental conflict," "hysteria," "time-limited mental health care," "short-term psychotherapy," and "acute grief." These early studies laid the foundation and provided support for many important crisis intervention concepts, including objective mediation, prioritizing patient treatment over problem diagnosis, directly addressing an individual's crisis, and the use of advanced empathy. It is generally recognized that the current field of crisis intervention, theory, and practice began with the groundbreaking efforts of Eric Lindemann (1944) and gained momentum through the work of Erickson (1963), Caplan (1964), and Quierdo (1968). Their numerous studies examined the effects of accidents and disasters on human functioning and shed new light on trauma response, crisis theory, and intervention practices. However, since the original work of these early pioneers, very few new theoretical approaches have been proposed to advance the crisis field (Hoff & Adamowski, 1998). Implications from their theories and practice are so fundamental that virtually all scholars and practitioners in the crisis field rely on their major concepts as a foundation (Hoff, 1995).

Grief postponement. In the early 1940s, 493 people were killed in the Boston Coconut Grove fire. Lindemann (1944) provided psychological assistance to individuals in various states of crisis, and his well-known study of the acute grief caused by this crisis provided the foundation on which the current understanding of crisis reactions is built. Lindemann identified five main characteristics of grief, including somatic distress, preoccupation with grim images, guilt, hostility, and loss of patterns of conduct. He discovered that acute crisis situations trigger similar patterns of grief and that individuals who were supported in expressing their grief experienced rapid stress relief.

Lindemann (1944) highlighted the seriousness of grief postponement, which is a type of crisis that occurs when a person displays little or no reaction to a tragedy, and noted the common experience of seeking to avoid the intense pain and distress associated with grief and loss. He concluded that, without intervention, denial and grief postponement were likely to lead to the development of personality disturbances, morbid reactions, and maladaptive behaviors. Lindemann's studies established a sequence of probable reactions and predicted how individuals might proceed through a crisis, depending on their reactions to grief. Later studies examined the effects of crisis-related stress on the human body and revealed that crises are detrimental to a person's physical health as well as his or her mental well-being. Current application of Lindemann's theories on acute grief, psychosomatic illness, and the crisis response emphasize the importance of immediate intervention, debriefing, and postvention efforts in order to lessen the long-term impact of crises.

Typologies of crisis. Erickson's (1963) work concentrated on the typologies of crisis. In particular, Erickson extended early definitions of crisis to include changes that occur naturally throughout the human growth and aging cycle and arise from situational, developmental, or sociocultural sources. According to Erickson, there are two categories of crisis: (1) maturational developmental crises, which involve physical, social, and emotional changes that occur because of the natural aging process and (2) accidental situational crises, which involve trauma and/or unexpected loss triggered by an unpredictable situation that taxes an individual's normal coping mechanisms. These categories of crisis also have been referred to as "internal" or "external" crises.

Situational crises are triggered either by a single, specific occurrence or by a compounded series of events, and typically, these occurrences are universally recognized as crises. These potentially traumatic crisis events can be classified in one of the following six categories (Brock, Sandoval, & Lewis, 2001; Slaikeu, 1990): (1) severe illness or injury; (2) violent and/or unexpected death; (3) threatened death and/or injury; (4) acts of war; (5) natural disasters; and (6) man-made/industrial disasters. Although Erickson's categories are still the primary classifications used today, Burgess and Baldwin outlined an expanded taxonomy that also includes crises associated with disposition, anticipated life transitions, psychopathology, and psychiatric emergencies (as cited in Hendricks & Thomas, 2002; Pitcher & Poland, 1992).

Mental health consultation. In 1946, Caplan joined with Lindemann to establish one of the first community mental health programs (Brock et al., 2001). Basing his theory on

Erickson's (1963) theories of life span development, Caplan (1964) believed that crises are often triggered by predictable developmental "tasks" that occur at various stages of life. Caplan suggested that failure to negotiate transitions from one developmental stage to another plays a role in the development of psychopathology and that personal and social resources are the key to determining how an individual resolves both developmental and situational crises. The concept of preventative mental health stemmed from the notion that because developmental crises could be anticipated, they also could be prevented (Pitcher & Poland, 1992).

Caplan (1964) also was one of the first theorists to address the concept of homeostasis, suggesting that people constantly employ coping strategies to maintain emotional equilibrium. Thus, he viewed crisis "as an upset of and an inability to maintain a steady emotional state" (Caplan, as cited in Brock et al., 2001, p. 12). Caplan suggested that crisis overwhelms an individual's normal problem-solving strategies and creates a state of disequilibrium associated with the inability to maintain emotional control.

Psychological first aid. Quierdo (1968) conducted studies during the 1930s in postwar Amsterdam, and his research determined that the effectiveness of crisis intervention is directly related to the intervention's proximity in both time and place to the crisis event. Quierdo's method, referred to as emergency first aid, was used extensively by the military during the Vietnam War, Korean War, and World War II. According to Hendricks and Thomas (2002), "[S]oldiers suffering from combat fatigue were sent to the rear of the combat zone to receive support. Research indicates that these soldiers were successful in regaining equilibrium within their immediate, albeit threatening, environment" (p. 12). Today, Quierdo's method is referred to as psychological first aid and is considered synonymous with crisis intervention.

Review of the Literature

Evaluation of Crisis Intervention Efforts

Crisis intervention is a relatively new responsibility for school systems in the United States. Prior to 1990, responsibility for school crisis intervention was not clearly defined; community mental health professionals, in fact, provided the bulk of mental health care for students impacted by crises (Johnson, 2000). However, schools are now increasingly relying on professionals within school systems for crisis intervention services (Brock et al., 2001; Johnson; Poland, 1994). Although there is heightened emphasis on crisis response in the schools, the field of school crisis intervention is still in its infancy. As a result, research, education, and training have not kept pace with the mounting need for the application of crisis intervention skills in the schools, and many school professionals feel they have inadequate training for the crisis intervener role (Allen, Jerome et al., 2002; Brock et al., 2001; King et al., 2000). This growing need for crisis preparedness and trauma response has highlighted the need for school counselors to develop specialized crisis intervention skills.

Although empirical support for the long-term effects of crisis intervention programs is unavailable, numerous qualitative accounts of school personnel who have "weathered" actual school crises attest to the value of having well-trained crisis teams and structured response efforts in place (Brock et al., 2001; Decker, 1997; Pitcher & Poland, 1992; Poland & McCormick, 1999; Trump, 1998; Wanko, 2001). Subsequent reviews of trauma response in the schools demonstrate that children who are able to verbalize their feelings and reactions in a timely manner recover most quickly and are better able to deal with the crisis in the long term.

A summary of crisis intervention and critical incident stress management research (Mitchell, 2003) yields the following conclusions in support of early intervention and debriefing efforts: multifaceted approaches to intervention are most effective; training, skill, and leadership style can impair or enhance the success of a debriefing; appropriate training determines the effectiveness of interventions; and when implemented effectively, debriefing reduces the signs and symptoms of distress associated with acute psychological crisis.

Furthermore, research indicates that the absence of effective intervention causes the crisis victim/survivor to reach a physical and psychological breaking point and increases the likelihood of permanent or long-term damage (Hendricks & Thomas, 2002; Palmatier, 1998; Poland & McCormick, 2000; Terr, 1983, 1992; Weinberg, 1993). The "Chowchilla bus incident" provided groundbreaking support for the importance of postvention services for victims of trauma. In Chowchilla, California, in the early 1970s, a busload of schoolchildren was kidnapped and buried underground for 27 hours. After their escape, no mental health care or counseling support was provided to the victims. As a result, follow-up and review of the incident indicated that, 5 years later, 100% of the children had clinical symptoms of depression, fear, and anxiety (Terr, 1983).

Additional research supports the improbability of adolescents being able to integrate traumatic experiences adequately, including suicide attempts or completions, without appropriate intervention and postvention efforts (Gilliland & James, 1997; Palmatier, 1998; Poland, 1994; Poland & McCormick, 2000; Terr, 1983; Weinberg, 1993). Moreover, if appropriate intervention and postvention activities are

not carried out, Gilliland and James suggested, "[A]lthough the original crisis event may be submerged below awareness and the individual may believe the problem has been resolved, appearance of new stressors may bring the individual to the crisis state again" (p. 6).

Since few intervention and prevention programs have been evaluated rigorously enough to conclusively determine the most effective approach, the Centers for Disease Control (CDC) and Prevention (as cited in Brener, Krug, & Simon, 2000) recommended that programs not rely on any single strategy. Pitcher and Poland (1992) recommended that prevention efforts begin with programs that address the major causes of death for children: accidents, homicides, and suicides. The most effective programs will involve multiple stakeholders and utilize multifaceted approaches that target specific at-risk behaviors in addition to addressing attitudes and skills that can serve as protective factors. Integrated prevention models and universal interventions, applied to everyone in the same manner and degree, maximize the cost-effective use of school resources and

> provide an ideal means for school settings to develop, implement, and monitor a comprehensive management system that addresses the needs of all students . . . it is a fair system in that normally developing students are not penalized by being denied access to potentially beneficial interventions. (Sprague & Walker, 2000, p. 376)

Suicide prevention programs. Suicidal thoughts and behaviors are so closely linked to the crisis experience (e.g., suicide can lead to a school crisis and a school crisis can lead to suicide) that suicide prevention efforts are integral to comprehensive crisis management. Suicide is widespread among school-aged children. Prevention programs increase the likelihood that students at risk for suicide will be more readily identified and assessed, in order to receive the services they need. School-based programs can be effective in increasing knowledge of suicide, dispelling myths related to youth suicide, reducing suicidal ideation and behavior, and promoting expectancies for engaging in help-seeking behaviors (Thompson, Eggert, & Herting, 2000).

In response to the lack of current prevention and intervention programs, the *Youth Suicide Prevention Plan for Washington State* recommended comprehensive education and prevention programs for youth, screening students for suicide ideation, training teachers as gatekeepers, and helping high-risk youth with support groups, drug programs, and life-skills training (Hayden & Lauer, 2000). Indeed, comprehensive, systematic, and multifaceted approaches to prevention and early intervention, involving both students and staff and including curriculum-based and staff in-service programs, have been consistently recommended in the literature (Dwyer, Osher, & Hoffman, 2000; Garland, Shaffer, & Whittle, 1993; Hayden & Lauer; Miller, Eckert, DuPaul, & White, 1999; Mitchell, 2003).

However, many suicide prevention programs are out of date with current scientific knowledge and, thus, are patterned after universal stress models, which maintain that suicide is simply a response to an extremely stressful situation (Popenhagen & Qualley, 1998). Therefore, Garland et al. (1993) recommended program components that sensitize and train school staff to have better understanding of the factors that increase the likelihood of crisis and the risk of suicide and that teach participants to more reliably identify and provide resources for high-risk youth. The most commonly included topics in existing prevention programs include suicide facts and warning signs, death/dying education, signs of emotional disturbance, psychological development in adolescents, accessing community resources, confidentiality issues, stress reduction/coping strategies, and interviews with suicide survivors and attempters.

Barriers to Crisis Intervention Efforts

Despite evidence to the contrary, many school personnel erroneously believe that a crisis cannot happen in their school and unconsciously detach themselves from crisis training and planning activities. These schools function in a reactive mode, minimizing the importance of preparation efforts and postponing prevention activities. Their behavior is guided by a false sense of security, and as a result, the school community is left vulnerable. It is important to understand that crises can and do happen in all types of school communities. After a well-publicized crisis or tragedy occurs, parents, community leaders, and school officials all over the nation begin to cry out for increased efforts at school security and crisis response. However, once the fear begins to subside and the immediate threat begins to fade, they often lack the sustained motivation to follow through with thorough planning, training, and preparation activities.

Many schools are ill prepared to prevent, intervene with, and follow up with students in crisis. For example, in a survey of 163 school districts in Washington State, Hayden and Lauer (2000) found that the majority of districts did not have suicide programs, policies, or procedures, and they were not actively involved in prevention or intervention efforts. Their research indicates that the largest perceived roadblock to implementing suicide programs is insufficient staff and the greatest perceived need is additional information and training. Although research has shown that school counselors are knowledgeable about risk factors, they still do not feel confident in their abilities to recognize at-risk

students and have indicated a need for more effective preparation in suicide and crisis intervention (Coder, Nelson, & Aylward, 1991; Fitch, Newby, Ballestero, & Marshall, 2001; King, Price, Telljohann, & Wahl, 1999, 2000).

A U.S. national survey conducted by Berman revealed that few professional schools, including programs for health and other human service professionals, incorporated formal coursework on crisis theory and practice (as cited in Hoff & Adamowski, 1998). Hoff and Adamowski believed every person working in human services, including school counselors, should understand the basic concepts and practices of the crisis model. Although feedback from school counselors suggests that recent graduates are receiving more preparation for crisis intervention than in the past, almost one third of school counselors continue to enter the profession with no formal course work or supervised experiences (Allen, Burt, et al., 2002).

The most common reaction to a crisis is to ignore it due to lack of training and awareness or fear that a response will worsen the situation and result in criticism (Klicker, 2000; Poland, 1994). Crisis intervention activities are often neglected due to lack of knowledge, overreaction, denial, or paralysis by analysis (overthinking to the point of inaction). Misconceptions of the problem and ineffective strategies inhibit crisis prevention and intervention efforts (Trump, 1998). Furthermore, reluctance to commit to comprehensive crisis intervention efforts is frequently linked to costs, to the stigma involved, to the logistics of putting on a program, and to a lack of understanding of the associated mental health issues (Tierney, Ramsey, Tanney, & Lang, 1990).

The Evolving Role of the School Counselor

It is apparent that increasing numbers of students are experiencing extreme mental and emotional pain that is influencing how they relate to themselves and others (Fryxell & Smith, 2000; Hazler & Carney, 2000; Minden, Henry, Tolan, & Gorman-Smith, 2000; Sandhu, 2000). Counselors must strive to formulate and adhere to visions that foster the intellectual, physical, emotional, and psychological well-being of the entire school community. As the role of the school counselor changes, counselors must adapt to support the new vision of school counseling. According to the American School Counselor Association (ASCA; 1997a), responding to and advocating for the emotional needs of all individuals impacted by crisis is part of the professional school counselor's role. School counselor involvement in crisis management efforts demonstrates a proactive commitment to ensuring that every student acquires the safety and survival skills necessary to emerge from a crisis stronger, more resilient, and better prepared to cope with difficulties in the future (ASCA, 1997b).

According to Sears and Granello (2002), "the preparation of counselors with individual and group counseling and guidance skills for academic, career, and personal/social counseling continues to be necessary, but is no longer sufficient" (p. 170). In light of the current emphasis on crisis response in the schools, Sears and Granello encouraged school counselors to develop the leadership skills necessary to impact systemic change and to transform school counseling to better meet the increasingly complex needs of today's school communities. As expectations for school crisis response and preparedness continue to increase, "educators must further their ability to consciously reflect on the provision of these services. Soon it will no longer be acceptable to respond in a reflexive fashion to crisis events . . . school crisis preparedness will be expected" (Brock et al., 2001, p. 7).

Professional literature is consistent in stating that school counselors should play a vital role in preventing and minimizing the impact of crises by advocating and providing leadership for crisis intervention and suicide prevention efforts (King et al., 2000; Remley & Sparkman, 1993). School counselors are the "experts" regarding student mental health issues and should be responsible for educating school personnel and helping them effectively deal with these concerns (King et al., 1999). Most school counselors feel that it is their role to identify and intervene with students at suicidal risk and that doing so would reduce the chances that the student would commit suicide (King et al., 1999). Thus, school counselors have an ethical, and, in many cases legal, responsibility for taking appropriate steps to effectively identify at-risk students, recognize potential lethality, and intervene with students in crisis.

According to Hoff and Adamowski (1998), "Excellence in crisis care requires appropriate education and training, access to consultation, and smooth interagency coordination" (p. xiii). Crisis intervention requires the acquisition and application of specific knowledge, attitudes, and skills in order to intervene effectively. Appropriate crisis management training should include the following: (1) knowledge of the nature of crisis and crisis responses, assumptions, and logic necessary for dealing with a crisis; (2) a general model and practical guidelines to prepare schools for crisis situations; (3) information on implementing a crisis plan; and (4) preparation activities, including role-plays and crisis drills. Furthermore, school counselors should be knowledgeable about the nature and extent of adolescent suicide; the warning signs and risk factors for adolescent suicide; student at-risk profiles; appropriate prevention, intervention, and postvention techniques; and the available mental health resources in the community (King et al., 2000; Popenhagen & Qualley, 1998; Remley & Sparkman, 1993).

Ethical and Legal Considerations

According to Decker (1997), schools have both a moral obligation and a legal responsibility to provide for the protection of the life, health, and property of students, faculty, and staff in emergencies. The *No Child Left Behind Act of 2001* (U.S. Department of Education [USDE], 2001) requires schools to anticipate acts of violence, be prepared to work through and manage crises, and ensure safety and order by implementing programs that protect students and teachers, encourage discipline and personal responsibility, and combat illegal drugs. To that end, districts must use federal school-safety funding to establish plans that include appropriate and effective discipline policies, security procedures, prevention activities, student codes of conduct, and a crisis management plan for responding to violent or traumatic incidents on school grounds (USDE).

School counselors should document and keep accurate records regarding consultation, notification, and intervention efforts with at-risk students. When there is a reasonable expectation that a student intends to do harm to self or others, counselors must disclose this information. According to Stone and Dahir (2006), "the school counselor's legal liability ends when school authorities or parents have been notified that a student is at risk and appropriate actions have been recommended" (p. 313). Though confidentiality is clearly paramount to the school counselor's role, a student's right to privacy becomes secondary to the duty to protect students from harm. Therefore, ASCA's (1997a) *Ethical Standards for School Counselors* includes the following guidelines with regard to situations which pose a danger to self or others: (1) After careful deliberation and consultation, when possible, inform parents/guardians or appropriate authorities when the student's condition indicates a clear and imminent danger to the student or others; and (2) attempt to minimize threat to a student by informing the student of actions to be taken, involving the student in a three-way communication with parents/guardians when breaching confidentiality, or allowing the student to have input as to how and to whom the breach will be made.

Because standards within each state are not consistent, it is imperative that counselors familiarize themselves with their state guidelines as well as specific school and district policies. Hermann and Remley (2000, as cited in Capuzzi & Gross, 2004) noted that, even though school personnel are expected to take reasonable precautions to prevent harm to students, courts have been reluctant to assign liability for injuries related to self-harm or violence. These claims typically fail because much of today's school violence, including suicide, can be considered spontaneous acts of violence. However, schools should not allow this fact to create a false sense of security, as "a growing number of legal opinions have indicated that an unanticipated act of violence can be predictable and, thus, actionable under state law" (Capuzzi & Gross, p. 290). Thus, schools can best protect themselves by taking a proactive stance toward crisis management and establishing comprehensive prevention, intervention, and postvention efforts as well as policies and procedures that mandate staff development and training.

Practice

Caplan (1964) proposed a model of mental health consultation that has become the foundation of school crisis intervention programs and crisis response (Pitcher & Poland, 1992). His model involves a three-part approach to crisis that includes primary, secondary, and tertiary intervention efforts. Primary care, or prevention, focuses on reducing the incidence of crises. Secondary care, or intervention, involves the immediate provision of assistance to individuals experiencing a crisis. Tertiary care, or postvention, reduces the long-term effects experienced by those directly or indirectly impacted by the crisis. Furthermore, Caplan emphasized community responsibility in facilitating the recovery of those in crisis and he called

> for the community and its agencies to work together to assist individuals in need . . . advocates trained in crisis intervention do this by training and networking community programs and by promoting general community welfare through preventative programs and response efforts. (Hendricks & Thomas, 2002, p. 11)

Crisis Prevention

Primary prevention, in the form of education, training, consultation, and crisis intervention, is designed to reduce the occurrence of mental distress, reduce exposure to hazardous situations, and reduce vulnerability to crises by increasing coping ability (Hoff, 1995). The goal is to promote growth, development, and crisis resistance in both individuals and the community. Therefore, prevention refers to proactive attempts by school leaders to teach students new and/or improved coping skills before difficult or traumatic events occur or immediately after a crisis in order to minimize long-term effects. The ideal objective for educators, counselors, and human service workers should be to establish prevention programs so effective that crisis intervention will seldom be needed.

The intent of expanding the notion of what constitutes a complete, thorough education is not only to help students learn but also to help them function as productive members of both the school community and the larger

society. Character education programs are a key component of the implementation of the *No Child Left Behind Act* (USDE, 2001) and an integral part of the solution for improving school climate and creating a safe environment in which students can learn and achieve (Stone & Dahir, 2006). Classroom guidance activities as well as individual and group counseling efforts aimed at character education and focusing on the identified traits of students at risk for poor coping should begin in elementary school. Early prevention efforts aimed at increasing the resiliency of all students are more effective than waiting for suicidal ideation or specific warning signs to emerge.

In addition, counselors should take leadership roles in developing and providing workshops, staff development materials, in-services, and training opportunities to all stakeholders. Parent education programs designed to promote awareness of high-risk behaviors, such as suicide and violence, as well as strategies for increasing protective factors and accessing additional resources and support are an integral component of a comprehensive crisis management program. Similar programs should be offered to teachers, in order to prepare them to serve as gatekeepers. Clearly, age-appropriate guidance lessons and small and large group counseling units should be provided for all students, in addition to providing specific interventions for those identified as high risk.

Developmental approaches. Much time, effort, and money can be exhausted in the process of identifying at-risk target students with whom to intervene. In the meantime, comprehensive, school–wide preventative measures would ensure that all students are taught the skills necessary to deal with a wide range of social, emotional, and behavioral difficulties, before they escalate into serious crises. Hazler and Carney (2000) described a humanistic and developmental approach to intervention and prevention as one that targets general characteristics as they appear in anyone, as opposed to focusing on only those who demonstrate the most clear danger to society. It may be more effective to concentrate efforts on promoting healthy behaviors as opposed to targeting the elimination of specific, negative behaviors. Therefore, schools will need to move increasingly away from a focus on individual pathology to one that integrates human development theories and the risk and resilience literature.

Hawkins et al. (2000) suggested a prevention model based on a social development perspective and employing multiple strategies across multiple systems (e.g., family, peers, school, and community). An effective program seeks not only to reduce or eliminate risk factors but also to build and maintain protective factors that buffer against risk. Thus, the following competencies should be included in a comprehensive curriculum: interpersonal communication skills, assertiveness, goal setting, negotiation, managing multiple projects, group communication, multicultural sensitivity, and knowledge of sound nutrition and health practices (Likona, 2004; Palmatier, 1998). Also important would be topics related to general coping skills, including stress and anxiety management, problem solving, conflict resolution, and anger management. Guidance lessons that specifically explore perceptions of crisis and the crisis experience can be very effective and may include discussion of the following: What is a crisis? How does crisis occur? How do you feel during a crisis? Where do you go for support? What behaviors from others are helpful or not helpful when you are in crisis?

Bullying prevention. The bullying prevention program targets bullying behaviors at the school, individual, and classroom levels. Program components include assessing the nature, severity, and prevalence of bullying with anonymous surveys; targeting school areas requiring additional supervision; providing classroom lessons and rules designed to discourage bullying and intimidation; providing individual and group counseling to both perpetrators and victims of bullying; and inviting parents of students receiving counseling to participate in family counseling. Outcomes of the program have shown statistically significant reductions in the number of reported victimizations as well as fewer discipline problems, improved attitudes toward academics, and improvements in peer social relationships (Olweus et al., 1999).

Crisis Preparation

The creation and maintenance of safe, orderly, growth-oriented climates, in which students can thrive, requires commitment, collaboration, vision, ownership, and comprehensive preparation. In the midst of turmoil, a comprehensive, easily implemented plan helps crisis workers respond, in a timely manner, with confidence, and enables them to give their full attention to those in need of their assistance instead of wasting valuable time planning and making decisions. During a crisis it is difficult to think clearly, even for those in charge; people need direction, structure, and support. Cornell and Sheras (1998) highlighted the importance of leaders taking charge by assessing the situation, making decisions, giving directions to others, and supervising activities. Without proper preparation, including in-services, familiarization of school crisis plans, and crisis drills, the school crisis literature suggests that people become more afraid and disoriented and, as a result, less likely to do what needs to be done in a moment of crisis. School crisis plans establish interventionist roles and detail specific steps for reestablishing stability, providing support, and facilitating the needs of the school com-

munity (Klicker, 2000). According to Poland and McCormick (2000), advance crisis planning, at both school and district levels, minimizes chaos, conflict, and misunderstanding surrounding what should be done and who can do it when a crisis occurs.

Crisis intervention team. Bennis and Nanus (as cited in Hill & Hill, 1994) described effective leaders as "capable of achieving attention through vision, meaning through communication, trust through positioning, and [possessing] a willingness to self-deploy and empower others" (p. 28). The burden of crisis intervention activities will not fall solely on the counselors' shoulders if they take a leadership roles in developing comprehensive crisis intervention programs and promoting the visions of awareness and prevention in their schools. Collaboration, consultation, and the provision of in-service programs can help counselors generate gatekeepers among the entire school community. Counselors have a responsibility to teach parents, school personnel, and peers to recognize at-risk students and identify situations that may precipitate or exacerbate crises.

The key to managing crises is a crisis intervention team that is competent, capable, and adequately prepared to handle an emergency situation and a crisis management plan that clearly specifies the team's goals and responsibilities. Crisis intervention teams typically consist of some combination of teachers, parents, counselors, social workers, school psychologists, school nurses, and school administrators. Team members should be taught how to facilitate prevention efforts as well as how to respond to individuals experiencing a crisis or in need of postvention efforts (Capuzzi & Gross, 2004). School administrators must encourage familiarization of the staff with the plan, and team members must share a common vision, have well-defined roles, and be willing to work together in a coordinated manner.

Essential content for training crisis team members includes crisis definition and theory, types of school crises, childhood reactions to crisis and grief, direct intervention skills, and factors that affect both the severity of the crisis experience and the resolution of crisis responses. According to Gilliland and James (1997), effective crisis workers are energetic, sensitive to issues of diversity, organized, and systemically oriented; above all, they are optimistic in their outlook and philosophy of helping others. Crisis team members should also be flexible, adaptable, intuitive, multitasked, and able to think/react under pressure. Team responsibilities include developing an intervention plan, coordinating with community services, educating and training staff, monitoring plans, and conducting postvention activities. In addition, periodic in-service training, crisis drills, and role-plays and frequent utilization of the crisis response team will help to ensure the performance of the team and the continued effectiveness of the plan.

Training activities. According to Hoff and Adamowski (1998), there is a differentiation between training and teaching, and "the design of crisis training programs is a highly specialized area of practice, involving small group skills, effective communication style, and other strategies that are not easily mastered in didactic (classroom-based) instruction" (p. 99). Education and training in crisis intervention are best accomplished through the use of a variety of modalities of instruction: lecture, readings, role-plays, modeled role-plays, small group exercises, audiovisual resources, Internet sites, survivor stories, simulated interviews with suicidal students, and observations of experienced trainees by their less experienced colleagues (Hoff & Adamowski; Weinberg, 1993).

Lecture is typically viewed as the method of last resort because trainees can absorb essential written content through training manuals, handouts, and recommended readings or Web sites. In a study by Murphy (2004), students who had combined (didactic/experiential) crisis intervention training indicated higher levels of comfort, preparation, and confidence than those who had didactic training alone. This is consistent with recommendations in the literature that have suggested that limited training time is spent more efficiently on experiential/role-play activities (Gilliland & James, 1997; Hoff & Adamowski, 1998; King et al., 2000).

Role-playing crisis intervention scenarios is an essential component of a thorough training program and is emphasized as a central aspect of training by every certified crisis or distress center (Gilliland & James, 1997; Hoff & Adamowski, 1998; King et al., 2000). Role-play provides valuable opportunities to develop familiarity with various situations, practice crisis intervention skills, learn creative ways to deal with unexpected contingencies, and evaluate the efficiency of the response. Honest, constructive feedback is crucial to the process because it provides the opportunity to examine blocks to rapport, identify overlooked elements to the interaction (e.g., missed suicidal clues), and allows for objective interpretation of skills. According to Gilliland and James, a critical component of training is not just talking about problems but practicing the direct application of specific intervention skills. Simulating authentic situations enables team members to find out what works and does not work for them in the safety of a training situation and to receive constructive feedback concerning the effectiveness of their skills.

Murphy (2004) examined the impact of a 2-hour crisis intervention training module on school counselor education students' knowledge of crisis intervention and suicide pre-

vention theories and concepts and their skills for responding to individuals in a variety of crisis scenarios. Because of participation in the training, participants' knowledge of crisis intervention theories and concepts improved significantly. However, there was no concomitant improvement in skills. This finding is consistent with other findings in the literature that suggested knowledge of crisis intervention does not necessarily translate into intervention skill (Coder et al., 1991; King et al., 1999, 2000). Although more than half of the participants reported feeling more confident in their ability to *recognize* an individual at risk for suicide, more than half also indicated that they did not feel adequately prepared to *intervene* with individuals in crisis, further demonstrating the discrepancy between "knowing" and "doing," and lending support for the need for more skill-based training. Furthermore, although self-perceptions of confidence and preparation increased, skill measures indicated that students' abilities to produce the most facilitative responses to individuals in crisis did not change significantly. Thus, increases in knowledge and self-efficacy were not translated into significant skill improvement.

According to King et al. (2000), additional time should be spent on helping counselors develop the practical skills needed to identify and assess at-risk students. Similarly, Hoff and Adamowski (1998) highlighted the importance of helping trainees understand the structure and value of the role-play process, including the use of appropriate content and the responsibility of fellow trainees for providing useful feedback. The authors also suggested that trainers model a brief role-play, containing both strengths and weaknesses, in order to illustrate the format and provide helpful feedback for the group. In particular, Hoff and Adamowski advocated modeling a role-play requiring a lethality assessment because "trainees with little or no experience in addressing the issue of suicide find it helpful to hear an experienced person ask directly about the client's self-destructive thoughts and behaviors or emotional pain from abuse" (p. 111). King et al. recommended that school counselor preparation programs increase the coverage of practical information pertaining to adolescent suicide and utilize role-play scenarios to provide valuable skill-building experiences.

Training Content

The six core competencies necessary for effective Critical Incident Stress Management (CISM) are closely aligned with the roles of a professional school counselor (ASCA, 1997b) and are key components of crisis management in the schools. These competencies include (1) assessment skills, (2) strategic planning skills, (3) skills to aid individuals in need of assistance, (4) large group intervention skills, (5) small group intervention skills, and (6) follow-up and referral skills (Mitchell, 2003).

Core crisis content falls into three categories that lay the foundation for objectives that demonstrate acceptable knowledge, attitudinal, and skill outcomes (Hoff & Adamowski, 1998). These categories parallel the established domains of multicultural competence (Sue & Sue, 1999). Although crisis is a universal phenomenon, its manifestation and resolution is influenced by the values, biases, and assumptions of both the individual experiencing the crisis and the crisis worker. School counselors should be aware of their ethical responsibility for providing culturally appropriate crisis intervention services and demonstrating multicultural competence concerning awareness of their own values and biases, awareness of the worldviews of diverse clients, and the provision of culturally appropriate intervention strategies (Sue & Sue). Culturally appropriate intervention requires school counselors to be sensitive to issues of diversity, which may influence communication styles, emotional expressiveness, coping strategies, help-seeking behaviors, and social support. Thus, mastery of knowledge, attitudes, and skills requires school counselors to consider each domain within the framework of multicultural competence.

Hoff and Adamowski (1998) provided the following example: A trainee should be able to "*identify* the steps of the crisis management process (knowledge), *demonstrate* a nonjudgmental attitude in role play, and *apply* the techniques of assessing suicide risk or victimization trauma in a real or simulated case situation (skill)" (p. 77). The elements of core content for crisis training curriculum were derived from the collective experience and knowledge of nationally and internationally recognized crisis specialists, suicidologists, and crisis organizations, including the National Institute of Mental Health (NIMH), the National Organization for Victim Assistance (NOVA), the American Association of Suicidology (AAS), and the Life Crisis Institute (LCI).

Knowledge. The knowledge component of core crisis content is the easiest to master because there are extensive resources available for self-learning, including books, audiovisual materials, and Internet resources. Essential concepts that should be mastered by crisis workers include the following list adapted from Hoff and Adamowski (1998): (1) crisis theory and principles of crisis management; (2) suicidology; (3) victimology; (4) death, dying, and grief work; (5) principles of communication; (6) identification and use of community resources; (7) ethical and legal issues regarding suicide, crime, and victimization; and (8) team relationships and self-care in crisis work.

Familiarization with definitions, types, and characteristics of crisis should be at the core of effective crisis train-

ing strategies. Essential content that counselors should be trained on include crisis definition and theory, types of school crises, developmental reactions to crisis and grief, warning signs and characteristics of suicide, assessment of danger to self or others, crisis intervention/grief counseling strategies, and factors that affect both the severity of the crisis experience and the resolution of crisis responses (Breland, Brody, Hunter-Ebeling, O'Shea, & Ronk, 1993; Cohen & Fish, 1993; Davis et al., 1993; Weinberg, 1993).

According to Cohen and Fish (1993), specific areas of knowledge related to suicide include prevention and postvention activities, warning signs, coping techniques, crisis intervention, handling the returning suicidal student, dealing with the friends of suicide attempters or completers, the contagion hypothesis, and managing the aftermath of a teacher, famous pop-culture idol, or parent/family member suicide attempt or completion. Breland et al. (1993) believed that issues of denial and preventability, the emotional impact of suicide, steps to take when facing a suicidal student, how to identify and talk to a depressed or suicidal person, and postvention plans for responding to the aftermath of a suicide are also key elements. According to Davis et al. (1993), "learning how to talk to students about suicide may reduce adult fears about such discussions, while training in listening skills and available school and community resources may allow staff to fulfill their roles more effectively" (p. 265).

Attitudes. Core crisis content includes the following attitudinal outcomes for training, adapted from Hoff and Adamowski (1998): (1) acceptance of and nonjudgmental response to persons different from oneself and toward controversial, emotional, and/or value-laden issues; (2) a balanced, realistic attitude toward oneself in the provider role; (3) a realistic and humane approach to death, dying, self-destructive behavior, victimization, and other human issues; (4) coming to terms with one's own feelings about death, dying, and the potential for violence, insofar as these feelings might deter one from helping others; and (5) activating with conviction one's advocacy role in client empowerment.

Helping people in distress is not a value-free endeavor, and counselors must be aware of personal attitudes and beliefs that may present barriers to impartial and compassionate crisis response. According to Hoff and Adamowski (1998), "it is important to note that rejection of problematic or challenging clients or value-laden responses to them may arise from insufficient knowledge of the dynamics and ramifications of some psychosocial and crisis situations" (p. 83). The authors recognized that some practitioner attitudes may remain fixed but suggested that new knowledge often leads to the kind of empathy and flexibility necessary to intervene with distressed persons.

Skills. Knowledge of crisis concepts and nonjudgmental attitudes are insufficient, without the ability to intervene with distressed individuals systematically and effectively. According to Hoff and Adamowski (1998), skilled intervention involves guiding each person toward "problem solving, empowerment, and crisis resolution consistent with the individual's values and meaning system . . . [and helping] distressed people avoid negative crisis outcomes such as violence, alcohol and other drug abuse, or chronic emotional or mental disability" (p. 84). School counselors must be able to apply the techniques for comprehensive crisis management, which include assessment, planning, implementation, and evaluation.

The skills necessary to work effectively with people in crisis include the following list adapted from Hoff and Adamowski (1998): (1) communicating well, listening actively, questioning discretely, responding empathically, and giving appropriate information and direction; (2) prioritizing to ensure an organized, systematic intervention process; (3) mobilizing community resources efficiently and effectively; (4) implementing agency policy and keeping records accurately and efficiently; (5) using consultative and referral processes appropriately; and (6) carrying out crisis management steps while withholding judgment on controversial behaviors and not imposing values on the distressed individuals.

A knowledgeable, well-trained counselor should be able to assess the level of risk, build rapport, and actively intervene with the immediate emotional crisis. In addition, counselors should be able establish procedures for receiving referrals from staff and contacting parents, as appropriate. The ability to provide additional resources and referrals to community-based services and to follow up on any actions taken is also important.

Crisis Intervention

Crisis intervention is an organized approach to helping distressed people; it is a specific helping activity, with its own unique set of theories, skills, attitudes, and knowledge. Crisis intervention is related to but differs from psychotherapy in that psychotherapy tends to be longer term and directed toward changing a person's maladaptive patterns of thinking, feeling, and behaving. Typically, the goal of psychotherapy is personal growth, and the therapeutic relationship is not characterized by the same sense of urgency and immediacy necessary for effective crisis intervention (Pitcher & Poland, 1992). Due to its emphasis on short-term stabilization, crisis intervention has been referred to as "emotional first aid" or "psychological triage" (Brock et al., 2001; Myer, 2001).

Crisis assessment. Crisis assessment involves determining a person's vulnerability to and resources for managing

traumatic life situations, including the recognized standard of explicitly ascertaining current and past victimization trauma and risk of suicide (Hoff & Adamowski, 1998). Hoff (1995) proposed a model of assessment that involves two levels: (1) safety, which would include an exploration of the presence of imminent threat or harm as well as suicidal or homicidal intent, and (2) the ability to function, which involves consideration of an individual's personal and social characteristics and resources. Hoff's model has been described as a "vulnerability model" because crisis workers are able to assess an individual's overall vulnerability to a maladaptive crisis response by considering the nature of the hazardous event (an event that, in terms of timing and/or severity, stretches a person's ability to cope and increases susceptibility to a full-blown crisis response), the precipitating factor, and the person's reactions to the event (Myer, 2001).

Preliminary assessment and intervention should focus on a hierarchy of needs (e.g., survival, safety, food, shelter) before attempts are made to process the associated psychological distress. This is particularly relevant concerning intervention efforts in response to natural disasters, as restoring equilibrium requires first attending to an individual's basic survival needs. Clearly, physical healing must take precedence to emotional healing.

According to Hoff (1995), assessing a person's reactions to crisis includes examining the following distress signals: difficulty managing feelings, suicidal and/or homicidal behaviors, alcohol or substance abuse, trouble with the law, and an inability to utilize available assistance. Gathering information on a person's assets and liabilities with respect to family and social resources is essential in terms both of understanding family and social factors that may be exacerbating a crisis and of identifying possible resources and support that can be mobilized to help with the crisis.

Debriefing. Once an individual is determined to be in a state of crisis, there is agreement among crisis intervention scholars and practitioners that sound crisis intervention requires effective interpersonal communication, an ability to focus the client on the experience of the crisis, and skill in guiding an individual through the process of recovery (Hendricks & Thomas, 2002). The process includes but is not limited to debriefing, which is often referred to as Critical Incident Stress Debriefing (CISD). The common goal of debriefing models is to allow a semistructured format for traumatized individuals to discuss the details of the traumatic event they have experienced. This detailed processing of a crisis event is most frequently conducted in small groups, and since most of the principles are the same, the process can be viewed as "group crisis intervention." Debriefing should be initiated as soon as possible after a critical event occurs and typically involves listening, emotional support and catharsis, psycho-education about "normal" crisis response, and referral for follow-up counseling, as needed (Hoff & Adamowski, 1998). Crisis counselors should be able to anticipate and explain common crisis reactions as well as empathize with and validate the wide range of emotions experienced.

MEETU: A model for crisis response. The mnemonic "MEETU" (i.e., "I'm going to 'meet you' to provide assistance") is a helpful device for remembering the steps involved in psychological first aid (Brock et al., 2001):

Make psychological contact
Explore dimensions of the problem
Examine possible solutions
Assist in **T**aking concrete action
Follow-**U**p

Slaikeu (1990) characterized the just described mnemonic crisis intervention process as involving the following steps: (1) making psychological contact through empathy, warmth, and respect; (2) exploring dimensions of the problem, including direct inquiries about the immediate past (crisis precursors), the present (the crisis story), and the immediate future (crisis-related problems); (3) examining possible solutions by asking about the coping strategies already used, facilitating an exploration of additional coping techniques, and proposing other problem-solving options; (4) taking concrete action by facilitating implementation of solutions to crisis problems (if lethality is high, crisis intervener should assume greater responsibility for assuring that direct action is taken); and (5) establishing a plan to follow-up with the crisis victim.

School counselors need to listen actively, openly name and discuss taboo subjects (e.g., suicide, rape, or divorce) as soon as they become apparent, demonstrate empathy, and remain nonjudgmental. A skilled interventionist uses these behaviors to build rapport and lessen an individual's anxiety, thus allowing for the expression of vulnerabilities in a climate of safety, understanding, and acceptance. In addition, counselors should be prepared to provide individuals impacted by a crisis with specific information concerning the affective, cognitive, behavioral, physiological, interpersonal (Gilliland & James, 1997), and psychological responses to traumatic events, in order to help them predict and prepare for the various stages of the trauma response.

Although the characteristics of crisis are fairly universal, the manifestation of symptoms and the ability to intellectually and emotionally process the crisis experience will vary according to a student's developmental stage. Although a thorough discussion of age-related symptomol-

ogy is beyond the scope of this chapter, school counselors should be mindful of providing developmentally appropriate prevention and intervention efforts for various grade levels. Crisis management activities should be reflective of the types of services counselors are already providing. For instance, adolescents are more capable of "talk techniques," while younger children may benefit from artistic outlets or play counseling activities designed to more effectively facilitate their understanding of the thoughts, behaviors, and emotions associated with their crisis response. There are a multitude of structured games and activities to help younger children process difficult events. One example is the Crisis Intervention Game (ages 6 to 12), which helps professionals counsel children who are coping with the devastating effects and emotions caused by a trauma or crisis in their lives. The game is designed to help children explore their feelings, make positive self-statements, and understand normal reactions to crisis situations.

Suicide deaths. According to Bolton (1993), not all counselors are willing to state categorically that addressing the issue of suicide will not trigger suicidal behavior. However, suicide literature clearly stresses the therapeutic importance of being able to discuss suicidal thoughts and behaviors openly, in terms of understanding both the person's own suicidality and that of others. The issue then appears to be not whether suicide should be discussed, but rather how it should be addressed. Intervention after a completed suicide should reestablish immediate coping with survivors in a way that minimizes identification with and glorification of the victim (Brock et al., 2001). It is a mistake to mystify the suicide or categorize it as unexplainable. For example, instead of saying, "It doesn't make any sense, she had everything going for her," say, "There were obviously serious things troubling her that we may never know about" (Rouf & Harris, 1988, as cited in Brock et al., 2001).

Youth Suicide Prevention Services at Albert Einstein Medical Center in Philadelphia offers school-based postsuicide crisis intervention services. They recommend a proactive approach wherein crisis workers act quickly to assess students' needs and provide immediate support to alleviate the shock and fear experienced by survivors of completed suicide. Discussing themes of permanent and reversible loss, death, hopelessness, and problem solving can be integral to the process of dispelling myths related to suicide and addressing the inevitable confusion experienced by survivors. Following a suicide death, it is also important to plan for and establish short-term support systems, utilize support groups, and provide access to more in-depth evaluation or therapy (Carter & Brooks, 1990).

Common intervention errors. In order to determine the common limitations of helping professionals in responding to distressed and self-injurious clients, Neimeyer and Pfeiffer (1994) analyzed participants' responses to the items on the Suicide Intervention Response Inventory (SIRI). According to Neimeyer and Pfeiffer, 10% to 40% of the interventionists in their study committed significant errors in the treatment of potentially self-destructive clients. The goal of their study was to identify common themes underlying various frequently occurring errors and less than desirable responses, in the hopes that identification of such common themes might be used to focus professional education in a way to redresses these weaknesses.

Thus, categories of suboptimal responses were identified in relation to the following themes: (1) superficial reassurance, (2) avoidance of strong feelings, (3) professionalism, (4) inadequate assessment of suicidal intent, (5) failure to identify the precipitating event, (6) passivity, (7) insufficient directiveness, (8) advice giving, (9) stereotypic responses, and (10) defensiveness. Neimeyer and Pfeiffer stated, "the frequency with which these errors occurred in our sample is as much an indictment of professional education . . . as it is a statement about the skill deficits of these generally well-intentioned helpers" (p. 218). It is believed that thorough discussion and role play of these common errors (including examples of both desirable and undesirable responses) will provide valuable opportunities to correct deficiencies in these previously identified areas of weakness.

Sample statements from the SIRI, which could be used to develop brief role-play scenarios, include the following: "I decided to talk to you because I really feel like I might do something to myself . . . I've been thinking about suicide"; "I've tried going to a therapist once before, but it didn't help . . . Nothing I do now will change anything"; and "I'm so lonely, so tired [crying]. There just isn't anywhere left to turn." It is important to remember that significant errors in responding to these types of statements, which are commonly associated with the crisis response, were highlighted in the research. Therefore, school counselors are encouraged to familiarize themselves with the analysis of these common intervention errors and to utilize the questions and responses on the SIRI as valuable training and practice materials.

Postvention

Postvention, or tertiary prevention, involves the provision of services (e.g., debriefing activities) designed to reduce the long-term effects experienced by those directly and indirectly impacted by crises. According to Weinberg (1993), postvention is considered a form of prevention, as it is designed to block the occurrence of new tragedies in response to the triggering event and associated symptoms. The recovery process includes not only restabilization but

also learning new ways of coping with stress through positive crisis resolution (Hoff, 1995). An effective crisis resolution helps individuals compensate for past vulnerabilities and bolsters the individual with an expanded repertoire of coping skills that will serve as a buffer against future distress (Roberts, 1990). Therefore, crisis resolution involves cognitive mastery of the situation, the restoration of equilibrium, and the development of new coping strategies.

Students are more likely to be responsive to additional evaluation, treatment, and postvention efforts when the counselor has established sufficient rapport and trust by demonstrating empathy and utilizing timely, effective crisis intervention skills. School and community officials should be sensitive to the fact that the most painful and stressful aspects of crisis management frequently continue well after the initial incident has passed (Trump, 2000). In fact, postcrisis experiences can often be much worse than the original crisis event in terms of length, intensity, and strain. What occurs during the immediate aftermath of the crisis event determines whether the person is able to assimilate the experience effectively and, thus, prevent the occurrence of chronic, long-term symptoms.

Postvention activities should focus on helping students achieve a reality-based understanding of the trauma, including common themes and experiences as well as common psychological and behavioral symptoms. It is also important to reinforce and praise students for their courage in the face of trauma and to help them regain a sense of control and confidence in their ability to deal with crises in the future. Students need to understand that, although their memory of a crisis may remain, with time, the pain lessens and symptoms disappear. After the immediate crisis subsides, school personnel should follow up with the individual, make appropriate referrals, and connect him or her with additional resources in order to provide ongoing support and reinforce positive changes.

In practical terms, it can be helpful for counselors to identify individuals who seem to have had a particularly difficult time dealing with the crisis, and make reminder appointments on a calendar for checking in with these students at specified dates in the future. For instance, 2 weeks after an incident, when the immediacy of the crisis has died down, students may often feel isolated, as though everyone has moved on. Follow-up activities can be a valuable opportunity to communicate care and concern when a counselor "spontaneously" reaches out to see how the student is handling the recovery process.

Suicide contagion. The contagion issue causes many schools to be hesitant about engaging in appropriate postvention activities because the conditions under which students will imitate suicidal behavior are not clearly understood. Although contagion in the form of distress may occur among survivors and increase the risk of suicidal behavior, postvention activities can be a counteracting process (Carter & Brooks, 1990). Davis et al. (1993) wrote, "Research suggests that contagion is more likely when suicidal behavior is modeled without discussion. Discussion may reduce the contagion effect" (p. 267). Counselors must address issues and concerns related to contagion and dispel myths that talking about suicide will glorify the behavior and cause it to happen.

Postvention-as-prevention is successful when survivors are encouraged to express their personal reactions to and struggles dealing with a suicide death. Thus, potentially self-destructive feelings can be expressed, tolerated, and diminished in a safe, open environment. Honest discussions that address students' confusion and concerns and dispel myths associated with suicide reduce the likelihood of their becoming suicidal (Bolton, 1993; Leenaars & Wenckstern, 1998; Poland & McCormick, 2000).

Research on the contagion hypothesis suggests that teens closest to a suicide victim may be at increased suicidal risk for suicide attempts (Brent et al., 1989; Carter & Brooks, 1990). Some researchers advocate screening exposed students, particularly those who were friends of the victim, for suicide risk, and it is recommended that counselors pursue the survivors as opposed to waiting for them to seek help (Brent et al.; Carter & Brooks). Small group counseling, large group assemblies, dispelling rumors, and comprehensive debriefings are recommended following a student death (Cohen & Fish, 1993). Debriefings after a completed suicide should address the following: guilt and anger, the nature of grief, validation of common reactions, the individuality of experienced grief and the recovery process, opportunities for the expression of thoughts and feelings, and provision of additional resources and support services (Bolton, 1993).

Debriefing for crisis workers. Postvention tasks should include thorough debriefing for those directly impacted by the crisis as well as the crisis workers. Working with people in crisis is draining physically and emotionally, and those involved in the intervention must make sure that their own needs are being attended. Due to the severity of many crisis-producing experiences and the intensity of the crisis response, working with individuals who have been traumatized makes counselors vulnerable to secondary traumatization. Furthermore, as members of the community, school counselors are frequently personally impacted by the same crisis for which they are assisting others.

The risk of burnout is very high, and team members must work together to provide support, encouragement, and guidance not only to the victims of crisis but also to one another. Counselors must be willing to attend to their own issues of self-care, so it is helpful to have procedures

built into the crisis response plan that allow for rotation and replacement of "frontline" interveners and the integration of additional resources and/or outside assistance, as necessary. In addition, crisis workers need to be given the opportunity to share their personal feelings of both the actual crisis and the intervention process with other members of the response team. As is common practice for many emergency response professionals, all crisis workers should be encouraged to participate in debriefing efforts, regardless of whether they are exhibiting signs of compassion fatigue, burnout, or secondary traumatization.

In order to use each crisis situation as a learning experience, team members and relevant stakeholders should also meet to debrief the practical elements of the crisis management process. This meeting should occur in a timely enough manner for participants to remember specific details and clear impressions of the process but not so soon that their own crisis resolution is not complete. Feedback should be provided about logistical concerns, plan effectiveness, and the team's strengths and weaknesses. It is important to provide constructive feedback and suggestions for improvement, including areas where additional training is needed. Examining the effectiveness of comprehensive crisis management efforts provides a valuable opportunity to evaluate, revise, and improve current procedures.

Future Directions

Research assessing future school administrators' perceptions of the school counselor's role indicated that responding to crisis and working with teachers in crisis situations were of primary importance (Fitch et al., 2001). Furthermore, a survey of school staff perceptions of student support services rated crisis intervention roles, including serving on a crisis team and providing direct intervention services during crises, as very important (Watkins, Crosby, & Pearson, 2001). Counselor educators can use this information in preparing school counselors to better fulfill the expectations of their positions. Since school administrators and personnel view crisis management as an essential task for counselors, school counselors should make training in crisis management a priority and be proactive in educating the school community about the importance of developing and implementing comprehensive crisis management efforts.

According to Hoff and Adamowski (1998), "the growth of professionalism emphasizes the training of various experts across settings and provider disciplines. A major outgrowth of this trend is the development of the crisis model as a distinct body of knowledge and practice" (p. 7). An increased understanding of crisis theory and training in crisis intervention skills can increase the efficiency with which crises are both recognized and handled. Early recognition of potential crises encourages timely, proactive responses that may prevent or minimize the impact of crises. Crisis training thus will help to increase knowledge, skills, and confidence levels and maximize opportunities for efficient intervention (Poland & McCormick, 2000; Weinberg, 1993).

According to Cornell and Sheras (1998), weaknesses in leadership, problems in teamwork, and failings in responsibility often precipitate or exacerbate crisis situations in schools. School leadership contributes to the morale of students and faculty and influences the nature of the school climate. If counselors intend to be proactive advocates for their students, they must be instilled with a vision for leadership that allows them to campaign for the prioritization of crisis intervention activities in their school communities.

CONSULTATION AND COLLABORATION AS ESSENTIAL SERVICES FOR SCHOOL COUNSELING PROGRAMS

MICHAEL B. SALZMAN

University of Hawaii at Manoa

The intention of this chapter is to examine the nature and variations of *consultation* and *collaboration* in school settings. The chapter will focus on relevant research, the major models of consultation and collaboration, and the importance of multicultural and historical contexts in relation to the processes of consultation and collaboration.

Consultation and collaboration are essential functions of school counseling programs and essential skills for school counselors. This has been true historically and is true today as school counselors seek to develop comprehensive counseling programs that are integral to the mission of the schools and communities they serve. Three important initiatives have been articulated that conceptualize a vision of school counseling where all students are served programmatically. The *National Model for Comprehensive School Counseling Programs* is sponsored by the American School Counselor Association (ASCA), the *National School Counselor Training Initiative,* and the *School–Community Collaboration Model* all stress the need for collaboration within and outside the schools and for the provision of consultation services (Baker & Gerler, 2004).

Consultation (along with counseling, coordinating, and appraising) has been considered one of the essential services performed by school counselors, and *collaboration* has been described as an important aspect of all relationships (e.g., with parents, teachers, and community agencies formed by school counselors; Schmidt, 1999). Although there is a great need for further research on all aspects of the consultation process in schools, there is a mounting body of empirical evidence demonstrating the efficacy of consultative services (e.g., Sheridan, Welch, & Orme, 1996). The Council for Accreditation of Counseling and Related Educational Programs (CACREP) has recognized the importance of consultation.

Collaboration in problem solving is well supported in the school psychology literature as a model for service delivery and is consistent with directions in federal law and educational initiatives designed to improve student outcomes (Allen & Graden, 2002). Collaboration is a necessary part of a school counselor's job (Porter, Epp, & Byrant, 2000). Groups and individuals working collaboratively can achieve goals and overcome challenges that would be difficult for an individual to accomplish and generally have more power to change systems (DeVoss & Andrews, 2006). The Education Trust (2002) emphasized the need for school counselors to be team builders and collaborators by working with teachers, administrators, staff, students, family members, and the community in service of the school's mission. Indeed, the need for professionals to work collaboratively has increased in recent years because of ever more complex sources of psychological, economic, social, and physical stress that impact people's lives (Nugent & Jones, 2005). School counselors are well prepared for this role by virtue of their training in group processes and dynamics as well as basic communication skills.

Definition of Terms

The terms *consultation* and *collaboration* have suffered from some definitional imprecision in the counseling literature

(Kampwirth, 2006). For the purpose of clarity, it is useful to consider, first, bedrock dictionary definitions of the terms. The *Oxford Encyclopedic English Dictionary* defines consult as "to seek information or advice" and defines consulting as "to give professional advice to others" (Pearsall & Trumble, p. 309). The consultant, then, is a person who gives advice. The consultant, then, is a person who gives advice. *Collaboration* is defined as working with others cooperatively.

Efforts have been made to both differentiate and synthesize these terms as they relate to school-based practices. For example, Erchul and Martens (2002) described school-based consultation as "a process for providing psychological and educational services in which a specialist (consultant) works cooperatively with a staff member (consultee) to improve the learning and adjustment of a student (client) or group of students" (pp. 13–14). The process, according to this definition, helps the consultee through systematic problem solving, social influence, and professional support. The consultee, then, assists the client by selecting and implementing the interventions generated in the consultation process. This essential triadic relationship characteristic of school-based consultation is supported by other scholars (e.g., Brown, Pryzwansky, & Schulte, 2006; Friend & Cook, 2003). They understand the process as a voluntary one in which one professional helps another address a problem concerning a third party by helping the consultee develop attitudes and skills that will promote more effective consultee functioning with an individual, group, or organization for which the consultee has responsibility.

Gelso and Fretz (2001) considered consultation to be a professional service that uses knowledge of human behavior, interpersonal relationships, and group and organizational processes to help others become more effective in their roles. They have suggested that, regardless of work settings, the consultation process involves a client, a consultee, and a consultant. The consultation relationship and process is voluntary, nonjudgmental, and nonrestrictive in that the consultee is free to accept or reject any suggestions or recommendations made by the consultant. The focus of the process and relationship is on the client's problems. Nugent and Jones (2005) described various types of consultation: (a) consultation with other counselors and mental health professionals; (b) consultation with faculty, administrators, parents, or families in educational settings; and (c) consultation with staff members of community organizations serving mental health needs.

Hackney and Cormier (2005) found a wide divergence of views on consultation. They did find general agreement that consultation is a process whereby one professional assists a consultee with a work-related problem with a client or client system. The lack of definitional clarity of consultation has been noted for at least 20 years (Brown et al., 2006). This definitional imprecision may be due to the varying theoretical models of consultation used by consultants working in different fields and settings. Confusion may have been further exacerbated or perhaps clarified by the introduction of the term *collaborative consultation* (Idol, Paolucci-Whitcomb, & Nevin, 1986; Reyes & Jason, 1993). Consultation is an essential function of school counselors. In the service of clarity, it may be defined in simple terms as a process whereby the first party (consultant) assists the second party (consultee) in finding a solution to a problem that concerns the third party (client) (Nugent & Jones, 2005).

The term *collaboration* has been used to describe "those instances in which two or more people agree to take somewhat equal responsibility for the implementation of the interventions" (Kampwirth, 2006, p. 3), generated by an interaction between coequal parties who voluntarily share decision making in working toward a common goal. This view is consistent with Sheridan, Napolitano, and Swearer's (2002) description of collaboration as being characterized by a "diversity of individuals and vantage points working together as coequal parties, sharing in the identification of goals and solution of problems, and forging trusting relationships wherein resources, power, and responsibilities are shared" (p. 322).

In an effort to clarify the definitional imprecision, other scholars (e.g., Schulte & Osborne, 2003) differentiated the two services in terms of direct and indirect services. They described consultation as an indirect service where the consultant does not work directly with the client, whereas collaboration is a direct service where the collaborators share responsibility for the implementation of the intervention. Gladding (2006) compiled *The Counseling Dictionary* of "concise definitions of frequently used terms in counseling." In this compilation, *consultation* was defined as follows:

> A voluntary *relationship* between a professional helper and an individual or group that needs help. In such a relationship, the *consultant* provides assistance by *helping* to define and resolve a *problem* or potential problem of the *client*. Consultant relationships are defined as triadic (i.e., client, consultant, problem) and are *content* based, goal directed, and *process* oriented. (p. 35, italics added)

Interestingly, Gladding's *Counseling Dictionary* does not define *collaboration*.

Collaboration and consultation are similar in that they both involve professionals engaged in a problem-solving process that requires a relationship based on mutual respect, cooperation, and shared goals. Collaboration and consultation, however, differ in that they are separate processes distinguished by who delivers the intervention. G. Caplan and R. B. Caplan (1999) and Pryswansky (1977) attempted to dif-

ferentiate the two processes by stating that in consultation, the consultee delivers the intervention developed in the consultation process, whereas in collaboration, the responsibility for the implementation of the intervention is shared.

Consultation and Collaboration as Efficient Interventions

Although there continues to be a great need for further research on all aspects of consultation and collaboration, the practice of school-based consultation and collaboration is supported in the literature and by a mounting body of empirical evidence demonstrating the efficacy of consultative services and collaboration with school stakeholders (e.g., Brown et al., 2006; Elizalde-Utnick, 2002; Gutkin & Curtis, 1999; Porter et al., 2000; Wilkinson, 2003). A central goal of the consultation process is to enhance and empower the consultee systems and thereby enhance the students' well-being and performance. By enhancing and empowering the consultee, the consultation process serves both a remedial and a prevention function. That is, the severity of current client problems may be reduced, and similar problems in others may be prevented due to an increase in the awareness, knowledge, and skills of the consultee so that the environmental factors that elicit and maintain problematic behaviors may be altered or eliminated (Zins & Erchul, 2002). This preventative focus inevitably shifts the target of consultation away from individual students to entire systems such as classrooms, schools, and larger communities. This shift requires an analysis that attends to organizational variables such as decision-making processes, opportunities to feel a sense of belonging, and the availability of avenues through which young people can achieve a positive sense of significance as human beings that have value.

Collaboration within the school, school system, and community helps counselors identify and address the needs of students by accessing appropriate services to meet the identified needs. By collaborating with relevant agencies, counselors facilitate access to needed services for students and families. This is most important in rural areas where schools and communities often do not have the resources and funds to address essential needs (Schmidt, 1999). School counselors have a primary responsibility for developing comprehensive programs in order to address the needs of all students. Given the scope of this function, it is necessary to gain the cooperative support of other professionals and persons within the school system and community. Collaborative relationships should certainly be developed with parents, teachers, students, and other counselors in order for them to cooperate in the solution of problems and in meeting real needs. Counselors may also develop fruitful collaborations with nurses, psychologists, social workers, and community social service and health agencies. Consultation and collaboration may effectively and efficiently extend the reach of counselors to effect positive change and serve the best interests of the school and its students.

In the section that follows, a generic model, as well as theory-based models, of consultation will be reviewed. These theory-informed models are mental health (four types), behavioral, Adlerian, and organizational consultation. Table 31.1 provides an abbreviated summary of the theoretical foundations, target of consultation ("Who is the client?"), type of consultation/collaboration, relevant data, and other major ideas and issues related to these models of consultation.

Overview of Pertinent Theoretical Models and Perspectives

Commonalities: A Generic Model

In general, all models of consultation share certain functions and stages. Although definitional precision remains elusive, the most frequently employed approaches all stress the use of problem solving as the mechanism through which interventions are generated, the focus on work-related problems, and the view of participation in the consultation process as voluntary (Zins & Erchul, 2002). Kratochwill, Elliot, and Callan-Stoiber (2002) noted that the major models of consultation all emphasize enhancing the problem-solving expertise of the consultee within the triadic relationship of consultant–consultee–client. The counseling intern and practicum student may benefit by conceptualizing the process of consultation along the generic dimensions shared by most models. While some variations exist across different models of consultation due to their theoretical and historical antecedents, each phase of the process presents shared challenges. These dimensions or stages may be broadly categorized as *entry, assessment, intervention, evaluation,* and *follow-up.*

The *entry* phase presents challenges. The consultant must enter the consultee–client system. The entry phase must address the ethical mandate of *informed consent,* whereby the consultee is given all necessary information about the process in order to make an informed decision about whether to engage in consultation. Entry requires the consultant to fully explain the process of consultation and to define what confidentiality is and what it is not. Potential consultees need to be assured that the relationship is voluntary, nonhierarchical, and confidential. It is important that consultees be aware that consultation is an indirect service and that the consultant will not be working directly with the client, whereas in collaboration, responsibility for the implementation of the selected intervention

Table 31.1 Summary of Consultation Models

	Theoretical Foundations	Who is Client?	Type of Consult/Collaboration	Relevant Data	Other Major Ideas/Issues
Generic	Eclectic	Individuals, families, organizations	Problem solving All models stress problem solving	Problem definition, relevant data depends on guiding theories	Mutual respect, informed consent, shared expertise Cultural context Historical context
Mental Health	Psychodynamic theory	1. Individual client 2. Primary focus on consultee working on case 3. A program or organization 4. Effectiveness of consultee with organizations, programs	1. Client-centered case consultation *2. Consultee-centered case consultation 3. Program-centered administrative 4. Consultee-centered administrative consult problem solving	Assess level of knowledge, skill, confidence, objectivity regarding client, situation, issue	Consultee intrapsychic factors (e.g., theme interference, biases, feelings, attitudes, and beliefs) Cultural context Historical context
Behavioral	Classical, Operant, and Social Learning	Individuals, families, organizations	Consultee directed Problem solving	Contingencies of reinforcement, role models	Cultural context Historical context
Organizational	Systems theory Field theory	Organizations	Systemic approaches to organizational change. Organization as client Problem solving	Communication & decision making processes, organization norms & values	Subsystems, feedback loops, reciprocal causality Cultural context Historical context
Adlerian	Adlerian theory	Individuals, families, organizations	Collaborative, psycho-educational Problem solving	Purpose of behavior, "pathways to significance"	Social interest, mutual respect Cultural context Historical context

*Type most closely identified with Caplan (1970; Caplan & Caplan, 1999) and is synonymous with "mental health consultation."

is shared. The power of consultation lies in its indirect nature, in which the consultee emerges from the process with greater expertise and skills. In addition, the consultee is empowered with increased effectiveness in addressing a particular issue, such as classroom management, that may impact many students. The consultee must be informed that the consultation relationship may be terminated at any time by the consultee and that the consultee is free to reject any suggestions made by the consultant. In this phase and throughout the process, *mutual respect* is a necessary condition for a successful consultation. If the entry phase is not successfully negotiated, the consultation process is unlikely to be successful.

All models of consultation require that both consultant and consultee *assess* the nature of the concern in order to achieve a common understanding of the problem or challenge under consideration. The specific data collected and considered is largely a function of the theoretical foundation of the model used and of the identified client. Behavioral consultation, for example, informed by behaviorism and social learning theory, focuses attention on the contingencies of reinforcement and the available models that may serve to stimulate observational learning. Mental health consultation models, informed by psychodynamic theory, may focus on data relating to factors and tendencies within the consultee, such as expectations, themes, biases, and degree of consultee knowledge and confidence. Decisions about what data is relevant, what sources of data may be accessed, and the collection of relevant data lead to a clear *problem definition*. A clear problem definition focuses the attention and efforts of all parties in the process.

The *intervention* phase requires the generation of possible intervention strategies that may ameliorate, solve, or better manage the defined problem. The degree of collaboration in this phase may vary across models. In some models, the consultant may assume a more directive role in suggesting intervention, while in other models, the generation of the interventions may proceed through a cooperative brainstorming process that produces a large number of possible strategies to be evaluated and ultimately selected by the consultee. When the intervention is agreed on and selected, the consultee, with the support of the consultant, implements the intervention.

Evaluation of the intervention is the next challenge of the consultation process. The data required for a competent evaluation must necessarily be related to the defined problem or opportunity. At this point, new data may be generated by even an unsuccessful intervention leading to a reconceptualization and definition of the problem or opportunity that was the initial focus of the consultation. In such cases, the consultant and consultee may "loop back" to the assessment stage to reexamine the concern in the light of new data (e.g., family stress). If the evaluation indicates a substantial improvement in the consultee's abilities and the client's situation, then a *follow-up* process begins to support a gradual withdrawal of the consultant from the system.

This generic model is useful to understand the process of consultation. Variations are largely dictated by the theoretical assumptions informing different forms of consultation and by who the consultee and client are in the consultation process. These variations influence the type of data collected, the nature of the interventions generated, and the criteria used to evaluate the effectiveness of the consultation. Students in counselor education programs would be well advised to become well grounded in the predominant counseling and psychological theories that inform the consultation models as well as counseling practice. A student well grounded in theory will have the intellectual flexibility to apply illuminating and coherent systems of data gathering, assessment, intervention generation, and evaluation to their observations. The importance and utility of theory in school-based consultation was emphasized by Brigman, Mullis, Webb, and White (2005): "To be successful in the consultant role, school counselors must have a theoretical base and models from which to operate. Theory provides a basis for understanding what helps people change their attitudes, skills, behaviors and expectations" (p. 9). They note that all models of consultation, regardless of their theoretical basis, are similar in that they utilize a problem solving approach to help consultees with school-related problems. Four theory-informed models of consultation will be briefly considered and described now.

Mental Health Consultation

G. Caplan (1970, 2004), a leader in the development of community psychiatry, has been enormously influential in the field of psychological consultation. He viewed consultation as an effective means for the prevention of mental disorders. A fundamental assumption of his model is that that both intrapsychic and environmental factors are important in explaining and changing behavior. More than any other model of consultation, mental health consultation focuses on the importance of intrapsychic factors such as consultee feelings, attitudes, and beliefs (Brown et al., 2006). In their book *Mental Health Consultation and Collaboration*, G. Caplan and R. B. Caplan (1999) placed collaboration alongside consultation as a major tool for mental health professionals to infuse psychological and preventive principles into varied work settings They suggest that when mental health professionals are internal to an organization (e.g., school counselors), collaboration may represent a better fit with the circumstances than consultation. As noted, within the collaborative model, the collaborators assume joint responsibility for aspects of the process including the implementation of the selected intervention (Brown et al.).

Caplan (1990) thought that consultation with caregivers such as teachers, parents, and mental health professionals would reduce the need for more intensive mental health services. Caplan's influence on consultation has been significant. He conceptualized consultation as a nonhierarchical, cooperative relationship between professionals where each possesses his or her own expertise that may serve to inform effective interventions. In this conceptualization, the consultee is free to accept or reject any suggestions offered by the consultant and bears sole responsibility for carrying out any interventions.

Caplan (2004) distinguished between four types of consultation along two major dimensions (Brown et al., 2006): (a) whether the content focus of the consultation is a difficulty with a particular client or an administrative difficulty, or (b) whether the focus of the consultation is on providing information in the consultant's area of expertise or an improvement of the consulteee's problem-solving capacity.

In the case of *client-centered case consultation*, the process is essentially prescriptive in that the consultant assesses the client and provides information and expertise in order to assist the consultee in working more effectively with the client. In *consultee-centered case consultation*, the primary goal is to increase the skills and effectiveness of the consultee in working with the client and other clients with similar issues. In *program-centered administrative consultation*, the focus is on the development of a new program or the improvement of an existing one. In this case, an administrative/program counterpart of client-centered case consultation, the program or organization is the client and those responsible for it are the consultees. The consultant makes recommendations for program improvement and organizational development. Last, *consultee-centered administrative consultation*, analogous to consultee-centered case consultation, focuses on increasing consultee effectiveness and professional functioning regarding specific organizations, programs, or policies for which they bear responsibility.

Brown et al. (2006) suggested that of the four types Caplan (1970) delineated, consultee-centered case consultation is the type of consultation most closely identified with him and is synonymous with the term *mental health*

consultation. The primary goal in this type of consultation is the remediation of deficiencies in the consultee's professional functioning that are responsible for difficulties with a particular case. Caplan suggested four major categories that necessitate different actions on the part of the consultant: (a) lack of knowledge, (b) lack of skill, (c) lack of confidence, and (d) lack of objectivity.

Interventions are generated depending on an assessment of the source of consultee difficulties. If *lack of knowledge* is a significant source of consultee difficulties due to, for example, a lack of knowledge of psychological, social, or developmental factors, then an intervention designed to increase relevant consultee knowledge of these factors would likely enhance consultee functioning. This may be accomplished by supplying information to the consultee. If the consultant assesses that this need is pervasive in an organization, then the problem may be systemic, suggesting the need for a system level intervention such as providing professional development opportunities. If the consultee possesses the relevant knowledge but has difficulty in applying that knowledge, then the difficulties might be attributed to a *lack of skill* in applying that knowledge. In this case, the consultant may work with the consultee in identifying appropriate sources for skill development within or external to the organization. If a *lack of confidence* is assessed as a significant source of consultee difficulties, the consultant may work to encourage and support the consultee and to find sources of support and encouragement within the organization and profession of the consultee.

In Caplan's (2004) view, when supervisory and administrative subsystems are working well in an organization, the majority of consultee-centered consultation cases will be the result of a consultee's *lack of objectivity* (Brown et al., 2006). Caplan identified five intrapsychic contributors to this problem. A *direct personal involvement* of the consultee with the client may occur, for example, when a professional relationship crosses a boundary to a personal relationship that may confound professional objectivity and functioning. *Simple identification* may be another contributor to a lack of objectivity. This may occur when the consultee identifies with the perceived situation of the client and superimposes his or her own experiences and struggles onto the case of the client, thereby losing professional objectivity. Similarly, in the case of *transference* (a psychodynamic concept), the consultee imposes her or his past experiences and expectations onto the client, thereby missing the real nature of the client's difficulties. In such cases, the consultee engaging in transference may well be an important source of the client's difficulties. A fourth category contributing to a consultee's lack of objectivity, *characterological distortion,* is perhaps the most extreme example. In this case, there is an enduring aspect of the consultee's personality that interferes with professional functioning. A perfectionist consultee, for example, with a deep need to perceive himself or herself as completely competent, may react negatively to a client who is not doing well, thereby contributing to client discouragement and difficulties.

A fifth, related source of consultee's lack of objectivity is given central importance in Caplan's (1970) thinking. *Theme interference* represents an unsolved problem or perceived defeat that was experienced by the consultee. The consultee makes a syllogistic link between a perceived situation and an undesirable outcome that is seen as inevitable. Linking a "broken home" to inevitable behavioral difficulties may create expectations in the consultee that make behavioral difficulties more probable in a kind of self-fulfilling prophecy. The consultee may in fact be manipulating the situation to conform to his or her preconceived expectations. Theme interference is more likely to occur when a particular situation makes a theme resident in the consultee more salient, reflecting the assumption that behavior is a function of a person–environment interaction. In this case, the consultant may work with the consultee to demonstrate that given a particular circumstance (e.g., a "broken home"), an expected outcome is not inevitable. In cross-cultural and multicultural consultation, particular themes regarding "how *they* are" are potent sources of a lack of objectivity. Biases and stereotypes may be particularly destructive themes resident in consultees, as they may assign clients to stereotypical categories rather than perceiving them as unique human beings.

Caplan's (2004) contributions have had enormous impact. His work focused attention on the relevance of variables resident in the consultee (e.g., perceptions, feelings, and attitudes) that may impact his or her interactions with clients. His emphasis on the importance of consultee involvement in the problem-solving process supports the effectiveness of consultation in cross-cultural and multicultural consultation contexts.

Research has found that mental health consultation has produced positive outcomes (Medway & Updyke, 1985; Sheridan et al., 1996); however, Brown et al. (2006) noted that a continuing problem in consultation research is a lack of data documenting how consultation has been implemented.

Behavioral Consultation and Collaboration

Behavioral consultation (BC) is informed by the principles of behaviorism and the learning theories and empirical evidence upon which it is constructed (Conoley & Conoley, 1992). After reviewing the consultation outcome research from 1985 to 1995, Sheridan et al. (1996) found that there was a well-established empirical basis for behavioral consultation. They found that more research was conducted with BC than with other models, that BC studies used the

most rigorous experimental designs, and that BC tended to yield very favorable results (95% of the BC studies reported at least some positive results). The earliest models relied on the operant learning theory as a conceptual basis for consultation in schools. Since the 1980s, behavioral models of consultation have taken a more eclectic approach with the inclusion of classical and social learning theories into its conceptual framework. Behaviorists see behaviors as a function of the contingencies that support them (Kampwirth, 2006). A primary focus of data collection and analysis are the antecedent events and situations that occur prior to the behavior of concern (e.g., tantrum) and the environmental consequences of that behavior. Some children find unstructured activities such as recess to be anxiety producing. In order to avoid this anxiety-producing situation, the child may purposefully not complete the required work prior to recess. If the teacher then keeps the child in during recess (environmental consequences), the behavior is reinforced and will likely continue. Behaviorists assert that a behavior that is not being reinforced by the environment (including teachers, peers, and parents) will not continue. There is research that supports this approach. Wilkinson (2003), for example, found that behavioral consultation was effective in reducing "challenging behaviors" in the classroom.

So, as theory indicates which data are important, behaviorists collect and seek to understand how the environment may trigger and support behaviors of concern. While traditional behaviorism (Skinner, 1969) was not concerned with internal cognitive events, the importance cognitive mediation such as self-talk is now widely recognized (e.g., Meichenbaum, 1977; Schloss & Smith, 1998). Bandura (1977) and his development of social learning theory provided an additional emphasis on the role of observational learning and modeling in the acquisition of learning and behaviors. In Bandura's framework, cognitive constructs are important. Self-efficacy (the confidence that one can perform a task) and appraisal (the importance one attaches to a goal or task) are important influences on human behavior. It is important to recognize that, across cultures, behavioral reinforcements, as well as how people tend to learn, may vary. In Hawaiian culture, for example, the mode of observational learning is particularly stressed (Dela Cruz, Salzman, Brislin, & Losch, 2006).

Bergan (1977) and Bergan and Kratochwill (1990) developed a comprehensive model of behavioral consultation. Consistent with the generic approach to consultation previously outlined, the major steps in their model are (a) problem identification, (b) problem analysis, (c) plan implementation, and (d) problem evaluation. These scholars emphasize that, in all cases, the consultant should have expert knowledge in learning principles and should use social learning theory and the principles of behaviorism to analyze problems and to design, implement, and evaluate interventions (Harrison, 2004). Brown et al. (2006) refer to a *behavioral eclectic* model of behavioral consultation and collaboration that is informed by operant, classical, and social learning theories. The behavioral orientation emphasizes that behavior is contextual and cannot be understood when decontextualized. Relevant context(s) may not be immediately observable, but they can be accessed by a multiculturally competent consultant or collaborator. History is context. Culture is context. The historical and cultural contexts of behavior offer powerful antecedents and consequences that may escape the ethnocentric or uninformed consultant. Such attitudes or lack of knowledge do not enhance the likelihood of effective problem analysis or intervention in multicultural consultation (Salzman, 2005). An American Indian child may not want to behave in a manner that would diminish the status of others in his peer group in accordance with cultural norms. To assess this behavior as a "problem" would indeed be problematic.

An aspect of behavioral consultation that has produced some controversy is the degree to which the consultant directs the process, as well as consultee compliance with consultant recommendations. Bergan (1977) and Bergan and Kratochwill (1990) emphasized the importance of consultant control over the consultation process, rather than the more collaborative approach previously described, where consultant and consultee each enter the process with his or her own expertise relevant to the case or problem under consideration. In cross-cultural and diversity contexts, this emphasis could prove problematic. When the consultant is unfamiliar with the cultural or class context of the consultee and client, the accuracy of assessment and the effectiveness of interventions may be compromised. A consultant from an urban community may not comprehend the power of an impoverished rural context on behavior and perception. A due respect for the relevant expertise of all parties would reduce the probability of this type of error. A due respect for the limits of one's knowledge is a foundation of competence and wisdom.

Adlerian Consultation and Collaboration

Adlerian theory and its applications (see Ansbacher & Ansbacher, 1956; Dreikurs, Grunwald, & Pepper, 1998) inform another theory-based model of consultation. Brigman et al. (2005) have found that Adlerian theory offers a sound educational premise for use with both students and adults in school systems because "it is future oriented, collaborative, and realistic. It emphasizes social interest and the importance of contributing to society" (p. 10). Bedrock Adlerian principles include the following:

- "Reality" is subjective
- Equality between the consultant and consultee

- Encouragement: Courage is an essential quality
- Mutual respect and social equality
- Humans are social beings, and human behavior has social meaning
- Behavior is purposeful, guided by a "private logic," and goal directed
- Useful and "mistaken" goals of behavior
- Logical and natural consequences

Teachers informed by Adlerian principles strive to create democratic classrooms where students participate in developing the structure of the learning environment and the reasonable rules and consequences that guide responsible behavior. This may be accomplished by the consultant working with the consultee (teacher) in developing democratic practices in the classroom. Such practices may include establishing weekly class meetings that address problems and classroom goals. Rules and consequences for violating them could be determined by students under the leadership— but not domination—of the teacher. Since Adlerian theory posits that humans struggle to compensate for feelings of inferiority, a high value is assigned to developing relationships based on *mutual respect* and *social equality*.

Adlerian theory informs teachers that all young people seek a sense of significance. Positive (e.g., contribution to school community and real achievement) and negative paths (e.g., attention seeking and bullying) may be taken to achieve the goal of feeling that one matters and is a person who is indeed "somebody." Consultants can work with teachers (consultees) to develop opportunities for children to experience a sense of belonging to the class through contribution, service, and participation. Adler emphasized the central importance of courage and encouragement as an antidote to discouragement, which is the basic orientation from which mistaken, antisocial, and self-defeating goals of behavior (e.g., attention, power, revenge, and withdrawal) are pursued. Adlerians think that courage is required to seek challenging positive *pathways to significance* and that discouragement produces a tendency to seek "mistaken" goals in the striving for significance.

Teachers informed by Adlerian theory seek data that may help them understand the purpose of behaviors and learn to reorient clients away from *mistaken goals* to useful, meaningful, and responsible behaviors that help achieve goals that are healthy for the client, the community, and the planet. A well-constructed classroom environment offers multiple positive pathways to significance, thus addressing a core human need ("self-esteem") in ways that are not self-defeating for the client and not destructive to the larger community. Adler thought that children who receive encouragement, feel a real sense of connection and belonging, and are given the opportunity to develop their strengths would turn to the useful side of life. Such children develop *social interest*, courage, and the ability to make responsible decisions. Social interest is seen as that quality which motivates one to contribute to the greater good, the group or community (Ansbacher & Ansbacher, 1956). Interventions guided by Adlerian theory might focus on classroom and school organization where efforts are made to ensure that each child has meaningful responsibilities to help the class achieve its educational goals in a supportive, encouraging, and respectful environment.

Brown et al. (2006) acknowledged that "empirical support for the Adlerian approach to consultation is sparse" (p. 93). They did, however, find some support for parent–teacher consultation. They cited Palmo and Kuzniar (1972, as cited in Brown et al., 2006), who compared the effectiveness of Adlerian teacher-parent plus Adlerian group counseling with parent–teacher consultation alone, with Adlerian group counseling, and with a no-treatment control group on classroom behaior. They found that all treatment groups produced significant results based on teacher ratings. They also found, however, that only the parent–teacher consultation treatment significantly decreased troublesome classroom behavior based on classroom behavior observations.

Schmidt (1999) found that Adlerian and behavioral approaches to consultation are common in school settings where teachers or parents may be consultees. Gianotti and Doyle (1982), for example, used Parent Effectiveness Training (PET) with parents of children who were diagnosed as have "learning disabilities." They investigated parental attitudes, children's perceptions of parent behavior, children's self-concepts, and children's behavior in school using a pretest–posttest control group design. The study found significant differences on all four variables. Children of parents in the PET group scored higher on self-concept measures than the control group. Students whose parents were in PET were seen as less anxious about school achievement, and they had more self-reliance and sought more positive relationships with their teachers. Parents who participated in PET reported more confidence in their parenting skills, a greater awareness of the effect of their behavior on their children, a better understanding of their own needs, and that they were more willing to trust their children than parents who did not participate in PET. Two studies of Systematic Training for Effective Parenting (STEP), an Adlerian-based program, demonstrated some support for this type of consultation. Williams, Omizo, and Abrams (1984) showed significant positive changes in parents' attitudes after participating in a STEP program. The study, utilizing a pretest–posttest experimental design, produced results indicating that the STEP parents were more accepting and trusting after participation in the program, and they perceived their own behavior as more of a contributing factor in their children's behavior.

One of the primary goals of consultation is the prevention of mental health and behavioral problems (Brown et al., 2006). A strength of Adlerian consultation is its emphasis on prevention. By addressing core human needs, human problems may be prevented. What do young people really need? Adlerian theory addresses the core needs of feeling valued, significant, and respected, as well as a sense of belonging and usefulness. Problems may be fruitfully analyzed and interventions may be generated with such needs in mind. Counselors as consultants would be well advised to see the entire school as their client. The Adlerian approach offers a useful lens to analyze the school organization itself for its ability to address the basic human needs of its constituents by focusing on such variables as the availability of "positive pathways to significance" for all, opportunities for students to exercise meaningful responsibilities in their school community, democratic versus autocratic practices in the classroom and school, sources of encouragement and discouragement, and the degree to which *social interest* is nourished. By seeing the *school as client,* the consultant is engaged in *organizational consultation*.

Organizational Consultation

When the counselor sees the entire school community as the client, she or he is functioning as an organizational or process consultant. A consultation or collaboration problem-solving process may be approached by examining such internal systemic variables as (a) communications patterns, (b) clarity of roles and functions, (c) processes and procedures for group problem solving and decision making, (d) group norms, (e) leadership and authority, (f) intergroup (subsystems) cooperation and competition, (g) formal and informal power structures, (h) clarity and prioritization of organizational goals, (i) incentive and reward systems, and (j) organizational climate and health factors. External variables may exert a powerful influence on organizational change efforts, whether attempted through consultation or collaborative interventions. External variables affecting a school organization include (a) accrediting bodies, (b) union agreements, (c) legislation (e.g., "No Child Left Behind"), (c) community pressure groups, (d) community political organizations, (e) tenure laws, (f) environmental factors such as socioeconomic status of the surrounding community, and (g) cultural factors such as community values, beliefs, assumptions, and norms. The quality of school climate varies tremendously across the United States (Kozol, 1992), especially in environmental contexts (i.e., rural, urban, and suburban) that exert powerful influences on organizations that are embedded in them.

As in the cases of the previously discussed consultation models, the focus of the consultation or collaboration and the theoretical basis of the models used dictate the variables of interest and the relevant data needed to inform all phases of the process of consultation or collaboration (e.g., entry into the system and relationship development, problem analysis and definition, intervention generation and selection, and evaluation strategies).

The "client" in organizational or process consultation and collaboration is the system (organization or family) itself, where the consultant/collaborator contributes expertise to facilitate positive systemic change (Erford, 2003). Organizational consultation may be well informed by the previously—but briefly—outlined theoretical models. Organizational consultation is also a triadic model (consultant–consultee–client) that is informed by Lewin's (1951) *field theory* and by *systems theory* (e.g., Bertalanffy, 1962; Katz & Kahn, 1978). Brown et al. (2006) noted a review of the professional literature from a wide variety of applied fields within the social sciences that reveals a remarkable theoretical convergence in *systems theory* and its applications to understanding organizations, family therapy, education, and community functioning. These theoretical foundations emphasize that individuals and their behaviors are functionally interrelated with the groups, organizations, communities, cultures, and socioeconomic systems to which they belong. Lewin (1951) offered a simple formulation that human behavior is a function of a person/environment interaction $B = f(P \times E)$. *Systems theory* indicates that in a system where all elements are interrelated, causality cannot be seen in linear terms (where A causes B), but instead is complex and reciprocal, where all elements in a system influence all other elements as well as the system itself.

Bronfenbrenner (1979) emphasized the importance of context. Developmental–ecological models of human development rest on the principle that human development and its behavioral expressions are strongly influenced by context and that an analysis of an event or behavior cannot be conducted independently of the ecological–cultural–systemic and social context(s). The ecological model posits four levels for classifying context (Bronfenbrenner). This classification begins with those ecologies the child directly interacts with (microsystems), such as the family and school. It proceeds to social, cultural, and historical forces that, while operating at higher levels of abstraction (e.g., mesosystems, exosystems, and macrosystems), may powerfully impact human development and experience. The macrosystem represents the broadest level of systemic influence. This contextual force includes ideological and institutional patterns and events that define social reality and influence psychological experience and its behavioral manifestations. The macrosystem represents an overarching context that includes historical events such as colonization, decolonization, community, and cultural trauma (Salzman, 2001). The relevance to multicultural consultation

is clear—a people's and a person's history and culture are influential contexts that cannot be ignored without risking serious and perhaps harmful error at all stages of the consultation process.

Welch (1999, as cited in Kampwirth, 2006), offers a set of general guidelines that may assist organizational consultants and collaborators to solve systemic problems that may improve the ability of the school organization to achieve its mission to provide a quality education to all of its students. The acronym DECIDE outlines this generic process:

D. Define and clarify the situation. What is currently happening? What is not happening that needs to happen? Describe in behavioral terms what the problem/issue/challenge is and who is involved and impacted by it.
E. Examine the environment and the systemic variables (i.e., reward and incentive system) that could be contributing to the problem.
C. Create a goal statement that includes
    1. Behaviors: Describe actions and events that are concrete, observable, and measurable.
    2. Conditions: Where and under what circumstances will the change occur?
    3. Criterion: Set a standard that must be achieved.
    4. Duration: For how long should the change be carried out?

I. Invent an intervention plan: The plan should address what will be done to accomplish the goal statement. This process may include stakeholders brainstorming ideas in a free and nonjudgmental atmosphere, evaluating the brainstormed interventions through a cost–benefit analysis, and selecting interventions that would address needs and identified goals. In order to develop an intervention plan that has a high probability of success, it is important to evaluate the availability and accessibility of the resources needed to undertake the intervention.
D. Deliver the action plan: Implement the plan that was designed to achieve the goals that, if achieved, would improve organizational functioning.
E. Evaluate the intervention action plan: This should include both formative and summative evaluations.

"School climate" is an excellent focus for organizational consultation or collaboration. It has been described (Lehr & Christenson, 2002) as a relatively enduring quality of the entire school that is experienced by members. It is the atmosphere for learning and includes the feelings people have about the school and whether it is a place where learning can occur. A positive school climate makes a school a place where both staff and students want to be. School climate has been recognized as an important component of effective schools. Lehr and Christenson cited numerous studies that have documented the association of school climate with improved student outcomes (e.g., Hoy & Hannum, 1997; Kuperminc, Leadbeater, Emmons, & Blatt, 1997; Rumsberger, 1995). Varying descriptions of the components of this complex construct converge on the construction of a sense or order and discipline, parental involvement, staff dedication to student learning, high expectations for academic performance and behavior, caring relationships, and respectful interactions among all stakeholders (students, parents, teachers, etc.) in the system.

Reality demands that schools be places where people feel safe and where learning takes place that prepares students to function competently in the world. How these demands of reality are achieved may vary according to contexts (e.g., cultural, historical, and rural–urban–suburban) but may share certain characteristics that are based on meeting fundamental human needs. Can we construct school environments where all feel valued, respected, connected, responsible, challenged, supported, and recognized for positive effort and accomplishment? How would such a school look? What would be happening that is not happening now? What would not be happening that is currently happening? If we want to raise responsible, self-respecting young people, should we not develop mechanisms for their meaningful participation in the decisions that affect them, rather than being the objects of the plans and actions of others? Is it not possible to construct a better world beginning with the schools we depend on to educate and nourish our children and young people?

Levels, Targets, and Contexts for Consultation and Collaboration

The targets of intervention identified by Brown et al. (2006) include individuals, groups, organizations, and communities. Another important issue is the level and purpose of the intervention. Primary prevention is true prevention. It aims at enhancing the positive development and mental health of a general population assumed to be "normal." It is designed to prevent problems before they may occur, for example, by enhancing life and coping skills needed to address the problems and challenges that life inevitably presents. Primary prevention may focus on individuals (enhancing skills), groups (improving communication patterns), organizations (improving decision making), and communities (community development). Secondary prevention addresses the early treatment of problems before they become serious and have significantly negative consequences for the individual,

group, organization, or community. Such secondary-level interventions may include a mentoring system for students facing stressful transitions, job enrichment programs, and professional development opportunities for school personnel, as well as community development efforts designed to improve community environments. Tertiary preventions are remedial in nature. They address serious problems and dysfunctions in persons, groups, organizations, and communities. Tertiary prevention is perhaps better described as treatment. Consultation with a parent of a self-destructive child would be an example of a tertiary-level intervention. Organizational consultation or collaborative efforts to reduce dangerous gang violence would be an example of tertiary prevention at the group and organizational levels. Consultation and collaboration can be effective interventions in these cases. It is, of course, preferable to prevent problems before they occur. We can do this by proactively and intentionally acknowledging and addressing real human needs.

The Cultural Context of Consultation and Collaboration

Various theory-based models of consultation have been presented, and we must consider when Western-based theories are applicable in working with culturally diverse populations. Are the theoretical foundations of the models discussed in this chapter irrelevant to non-Western clients, consultees, and collaborators due to a Eurocentric bias in the foundational assumptions upon which these theories are constructed? Can they be effectively adapted in the service of multicultural consultation and collaboration?

The American Psychological Association (2003) published a set of six guidelines on multicultural education, training, research, practice, and organizational change for psychologists. These guidelines may assist consultants in considering how to think about cultural variation in the practice of consultation. The guidelines encourage us to recognize that we, as cultural beings, may hold attitudes and beliefs that can detrimentally influence perceptions and interactions with individuals who are racially, ethnically, and/or culturally different from ourselves. Stereotypical and prejudicial beliefs resident in a consultant, consultee, or client may confound the consultation process as indicated previously in the case of theme interference in mental health consultation. The guidelines also encourage us to recognize the importance of acquiring specific knowledge, skills, and understanding about culturally, ethnically, and racially different individuals in order to inform our practice.

Brown et al. (2006), for example, considered the cultural limitations of Adlerian theory and its approach to consultation with Native American, Asian, and Hispanic people due to different orientations to time, hierarchy, independence, and other variables that tend to vary across cultures. While cross-cultural differences exist and are important, in order to avoid the error of stereotyping we must acknowledge that within-group differences along these dimensions also exist. Perhaps culture, as well as other diversity variables, is best considered as a hypothesis to be tested. The power of a consultee to accept or reject consultant recommendations reduces the probability of error in these cases. The client in the triadic relationship is usually not afforded the same prerogative. Consultant and consultee can work to empower the client to have a voice in the process to the maximum extent possible when cultural differences exist between the consultee and client.

The theory-based models presented in this chapter may, however, be adapted in the service of effective multicultural consultation and collaboration. Salzman (2002) described a successful consultation at a Bureau of Indian Affairs Boarding School in a traditional area of the Navajo Nation in Arizona. The consultant emphasized one aspect of Navajo culture in order to address the defined problem. Traditionally, Navajos give great responsibilities to their children. Children make important contributions to the family by grazing sheep (family wealth), finding missing horses, or cutting wood for elders so they would be warm. When problems arise in the family, a family meeting is called where all members are expected to offer their views and contribute to a solution. This egalitarian, democratic, social, and social-interest orientation is resonant with aspects of Adlerian theory.

The problem as presented was the relationships among staff (Navajo) and students (Navajo) in the school's dormitory. There was conflict between the staff and the students, as well as conflict among the students. The Bureau of Indian Affairs system was a top-down command structure. Incident reports piled up, and people were miserable. The consultant met with dormitory staff and students to assess the problem. He called a mass meeting in the dormitory and offered the residents the option to take responsibility for running the dormitory consistent with two principles dictated by the demands of reality, which were nonnegotiable. These "nonnegotiables," which no one would really argue against, were that the dormitory must be safe for all and that it must be a place where studying and learning could take place. Students were asked to elect a representative council (also consistent with Navajo culture) and to determine what was needed to improve the situation. Navajo dormitory staff then assumed supportive roles in assisting the students in their task and efforts. The students determined what rules should exist to support the "nonnegotiable" requirements of safety and study, as well as the consequences that should be delivered by staff when the rules were violated. The staff quickly moved from the BIA

"command" system to a role more consistent with Navajo culture. After four visits where the consultant worked with the consultees (staff), the democratic structure developed by the students was worked on and refined to the point where the consultant was informed that the students were essentially "running the dorm themselves." Incident reports dropped dramatically, the students found ways to involve their parents, a newsletter was developed, and recreational and cultural events nourished the system. This scenario, abbreviated in its description, is an example of adapting a "Eurocentric" theory to a non-Western people by finding and utilizing compatibilities between the cultural and theoretical systems in all phases of the process.

As previously indicated, other theoretical systems may be adapted or modified in cross-cultural and multicultural contexts. Consequences that may be considered reinforcing in one culture may be aversive in another. Being singled out for praise or being elevated above the group by a teacher may bring negative consequences from the group in collectivist-oriented cultures (e.g., Navajo or Hawaiian). This same situation may be highly reinforcing to someone from an individualistically oriented culture.

Consultants working across cultures must access the historical and cultural contexts of their observations. Ridley, Li, and Hill (1998) remind us of two types of error that counselors need to consider when working across cultures. Type I errors may occur when a symptom or behavior is decontextualized from the client or consultee's culture thereby labeling a culturally appropriate response as pathological where no pathology exists. In this case, the cultural worldview and values of the consultant are imposed thereby interpreting the "symptom" or behavior according the cultural worldview of the consultant or counselor. This "pathologizing" error may have serious consequences as the label, erroneously applied, may be internalized by the person being labeled. A Type II error may occur when pathology is not identified when it exists because the behavior or manifestation is considered "cultural" and therefore "normal." Both types of error may have serious consequences. Ridley et al. offered a comprehensive system of multicultural assessment that might serve to minimize the likelihood of Type I and Type errors.

Consultants working across cultures must access the cultural context of the client and the consultee. This may be accomplished by seeking cultural consultants, reading, and inquiry. Consultants working across cultures may access traditional healers and resources within the culture of the client as a source of information that may serve to illuminate the analysis and definition of "the problem" and provide intervention possibilities in both consultation and collaboration processes. Culturally competent consultants and collaborators are aware of their own cultural socialization and that of the consultee, client, or collaborators.

Consultants working across cultures must access the historical context of the client and the consultee. Salzman (2005) looked at the symptom of "anger" among many Hawaiian people in the context of a history of colonization and the processes of decolonization and recovery. The symptom of anger may be viewed very differently when the historical context of anger is acknowledged or ignored. The approach to "anger management" would be quite different if one sees anger as a necessary force for psychological liberation from internalized oppression and for political emancipation. Another example would be the author's experience as a fourth grade teacher in a poor, tense, and stressed African American community in Brooklyn during the tumultuous year of 1968. Fortunately for the author, the politically aroused community gave an in-service to new teachers (mostly Euro Americans) about how parents tended to perceive teacher behaviors. These perceptions and attributions where highly influenced by a history of oppression and disrespect. The author remembers being told that parents tended to experience the phrase "these children" negatively. It was as if their children were considered inferior subspecies of children. This in-service given by the community allowed new teachers access to the cultural, historical, and political realities that contextualized behaviors and attributions.

Behring, Cabello, Kushida, and Murguia (2000) examined the use of current consultation approaches and modifications used by European-American, African American, Asian American, and Latino consultants and students. They found that consultants from all cultural backgrounds reported using modifications with teachers and parents for all cultural groups of students except the Euro American group. Interestingly, they found that non-European-American consultants reported using more and different modifications when working with culturally similar parents as compared with Euro American consultants. The results of this study strongly suggest that modifications to current consultation approaches must be used when working with non-European-American students and families. The modification most reported with teachers of non-European-American students was helping the teacher to develop an awareness of the students' cultural differences in the class. Other modifications included

> the consultant helping the teacher to develop an openness to discussing culture with students, the consultant helping the teacher to develop culturally sensitive skills with students, the consultant helping the teacher to allow more time for relationship building with the student and the consultant offering teacher support to cope with cultural differences of students. (Behring et al., 2000, p. 360)

A culturally competent consultant or collaborator seeks interventions that are appropriate and is respectful of the cultural orientation of those with whom they work.

Extant Research and Future Directions

Schmidt (1999) noted that while research on consultation is plentiful, methodological problems make it difficult to draw concise and accurate conclusions. Medway and Updyke (1985) averaged effect sizes over 24 studies examining the effectiveness of mental health, behavioral, and organizational consultation in a meta analysis. They concluded that all three models of consultation were effective across consultants, consultees, and clients. Brown et al. (2006) concurred, noting that methodological problems, fragmented studies, and definitional problems often characterize consultation research with the most frequent problem being the lack of control or comparison groups. In order to address the difficulty of finding appropriate control groups, because it is problematic to withhold a service that can be of immediate assistance to a consultee, these scholars recommended the use of time series research designs. They also stressed the need for outcome research "that measures multiple outcomes and is based on actual consultation efforts" (p. 326). In addition, in view of the continuing problem of definitional imprecision of consultation noted earlier, the theoretical propositions of the model should be elucidated to avoid atheoretical and therefore unreplicatible studies. Finally, Brown et al. suggested that consultation research mirror the complexity of the process using multiple measures of process and outcome dimensions of consultation involving consultee and client variable in order to establish interactions among independent and dependent variables. They further asserted that research cannot yet answer the question of which model of consultation is most effective for a particular problem. They suggested that the selection of a model of consultation should take into consideration the theoretical orientation and personal biases of the consultant as well as the nature of the presenting problem, the characteristics of the consultee, and the resources and constraints embedded in the setting.

Conclusion

School counselors are increasingly pressed to serve the needs of all students through comprehensive programming in the domains of career, academic, personal, and social development. At the same time the ratio of students to counselors is usually far beyond the capabilities of counselors to directly serve all students. Consultation and collaboration skills and services offer the possibility of reaching far greater numbers of students than individual counseling can achieve. This chapter has outlined generic and theory-based models of consultation and collaboration that will hopefully stimulate both beginning and seasoned counselors in their efforts to develop comprehensive school counseling programs that serve all students by helping them develop essential life skills that will empower them to meet life's challenges and the inevitable problems life presents. Consultation is effective because it can empower and improve the functioning of those whose actions affect many students (i.e., teachers, parents, and principals). Collaboration with other professionals, parents, community, and social service agencies combines the skills and expertise from diverse sources to address problems and needs. Both services may serve both the prevention and remediation of problems. Both services can positively impact individuals, groups, school organizations, and communities. Consultation and collaboration are essential and powerful services and competencies for school counselors to offer and cultivate in our efforts to construct a better world beginning with the schools that serve our children and young people.

XXXII
CAREER DEVELOPMENT INTERVENTIONS IN SCHOOLS

WEI-CHENG J. MAU
Wichita State University

Introduction

Historical Perspectives of Career Development in School Settings

Systematic vocational guidance in America can be traced back to the late 19th and early 20th centuries when social reformers saw the need of helping dislocated workers who flocked into urban cities because of the Industrial Revolution. Frank Parsons was one of the many persons who were striving to make the world a better place in which to live. His book, *Choosing a Vocation* (Parsons, 1909), and his tripartite model of vocational guidance have significantly impacted the theories and practice of vocational guidance for centuries. In his view, vocational guidance consisted of three steps: (a) develop a clear understanding of self, (b) develop knowledge of the requirements and conditions of work, and (c) use *true reasoning* relating these two groups of knowledge.

During the early 20th century, several forerunners had advocated the involvement of career guidance in school settings. Jessie D. Davis (1914), for example, was able to implement the tripartite steps — self-study, occupational study, and examination of self — in relation to students' chosen occupations throughout the 7th through 12th grades, while he was the principal of Central High School in Detroit. Anna Reed (1871–1946) established guidance services in the Seattle school system, and by 1910, 35 cities had plans to establish vocational guidance in their schools (Aubrey, 1977).

During the last 30 years, career education has been influential in the evolution of career services (Herr & Cramer, 1996). It was introduced as a federal priority by the U.S. Commissioner of Education, Sidney Marland, on January 23, 1971.

Career education is the systematic attempt to influence the career development of students and adults through various types of educational strategies, which include providing occupation information, infusing career related concepts into the academic curriculum, promoting various worksite-based experiences, and offering career planning courses (Isaacson & Brown, 2000). Since its introduction, there have been numerous attempts to translate the ideas into action, with funding from private and public sectors. Meta-analyses on the effects of career education intervention have suggested that career education has moderate effects (Baker & Taylor, 1998). Although the term *career education* is being used less frequently, the concepts it connotes continue to be viable and supported by a variety of federal and state programs (Hoyt & Shylo, 1989). Given the continuing need to help children and adolescents prepare for the transition from school to work, the career education goal that was first presented about three decades ago still seems to be salient.

By the late 1960s and early 1970s, the term *career guidance* began to appear in the literature as interchangeable with vocational guidance. The redefinitions and paradigm shifts associated with the emerging term *career guidance* were creating new metaphors. Career guidance was being termed a lifestyle concept that embodied the need to combine work and leisure counseling (McDaniels, 1978). Super's theory (1957) led to a paradigm shift within the career development field. In contrast to the Trait-and-Factor approach, which focuses on matching individuals with comparable occupations at a single point in time, Super's career development approach emphasized a lifelong development of interests, abilities, values, work, and leisure activities. Super's career development concept is especially helpful for school-aged students in understanding the stage-specific needs of these students and predicting

their future behaviors. As definitions of career and career development have evolved and become broader and more encompassing, particularly during the past 20 years, there has been a corresponding broadening and expansion of career guidance programs and services to children and young people in our schools.

Recent Development

Moving into the 21st century, we are faced with many different career developmental concerns in the school setting: increases in school population, increases in diversity of student population, and increases in emphasis on school to work (V. S. Solberg, Howard, Blustein, & Close, 2002). In responding to this demand, it is important that counselors have a clear understanding of the career development needs diverse student populations have and effective career interventions that are developmentally appropriate.

Career development is a lifelong process that starts the minute a child is born (Super, 1990). Perhaps the most critical point in a child's career development is when he or she is still in school, is active in learning, and is in a learning environment that provides a preventive/developmental approach. Research has shown that students are more likely to stay in school and engaged in learning when they see the relevance of their course work to career work (Lapan, Gysbers, & Petroski, 2001). For children and adolescents, their school and leisure activities represent their work. These activities provide essential learning experiences that shape self-perception and understanding of the world of work (Niles & Harris-Bowlsbey, 2005). Career counseling and education are critical components in a comprehensive counseling program in school settings. School counselors play a key role in facilitating the career development of students. Herr (1992) asserted that schooling, human development, and economic development are now linked in this nation in an irreversible fashion. Thus, connecting students' learning in school with the world of work is more important than ever. Students must demonstrate not only basic skills in reading, writing, and performing arithmetic and mathematical operations, but also demonstrate higher order thinking skills in making decisions and solving problems, as well as effectively applying personal qualities in self-management (U.S. Department of Labor, 1991). If our schools fail to graduate students with these skills, graduates will not be able to compete in the global marketplace.

School Counseling Standards

Increasingly, counseling practitioners are required to be accountable for the effectiveness of the services they provide. It is critical that school counselors be knowledgeable about the types of career interventions that have been proven effective. Another trend in school counseling is the utilization of standards-based, developmentally appropriate counseling approaches. The American School Counselor Association (ASCA) has established standards for career development of school-aged students. The standards related to career development are as follows:

- Standard A. Students will acquire the skills to investigate the world of work in relation to knowledge of self and to make informed career decisions.
- Standard B. Students will employ strategies to achieve future career success and satisfaction.
- Standard C. Students will understand the relationship among personal qualities, education and training, and the world of work.

The National Career Development Guidelines (National Occupational Information Coordination Committee [NOICC], 1992) described the personal competencies individuals should have in order to successfully manage their careers throughout their lives. The Guidelines, released in 1989, represented consensus among the government and leading career counseling organizations as to what is necessary to foster excellence in career development. The framework outlined the organizational and personnel requirements necessary for effective comprehensive career development, as well as the specific competencies that career development programs should be instilling. The Department of Education has recently revised the National Career Development Guidelines in order to bring them into alignment with the goals of the *No Child Left Behind* legislation.

National Career Development Guidelines

The newly revised guidelines consist of three domains: (a) Personal Social Development (PS), (b) Educational Achievement and Lifelong Learning (ED), and (c) Career Management (CM). The three domains organize content that is further described by 11 goals**.** The goals define broad areas of career development competency as shown here.

Personal Social Development Domain

- GOAL PS1 Develop understanding of self to build and maintain a positive self-concept.
- GOAL PS2 Develop positive interpersonal skills including respect for diversity.
- GOAL PS3 Integrate growth and change into career development.
- GOAL PS4 Balance personal, leisure, community, learner, family, and work roles.

Educational Achievement and Lifelong Learning Domain

- GOAL ED1 Attain educational achievement and performance levels needed to reach personal and career goals.
- GOAL ED2 Participate in ongoing, lifelong learning experiences to enhance ability to function effectively in a diverse and changing economy.

Career Management Domain

- GOAL CM1 Create and manage a career plan that meets your career goals.
- GOAL CM2 Use a process of decision making as one component of career development.
- GOAL CM3 Use accurate, current, and unbiased career information during career planning and management.
- GOAL CM4 Master academic, occupational, and general employability skills in order to obtain, create, maintain, and/or advance employment.
- GOAL CM5 Integrate changing employment trends, societal needs, and economic conditions into career plans.

In the standards-focused climate of today's schools, school counselors take a leadership role when they help administrators, teachers, parents, and others recognize the link between career development, academic development, and personal/social development of students. Professional school counselors play a critical role in the career development of school-aged students. Although some schools use professionals such as social workers to perform counseling interventions, professional school counselors are often the only professionals with specific training in career development (Niles & Akos, 2003). Professional school counselors possess knowledge of career development theory and skills of program development and implementation, which allows them to take a leadership role in the standards-focused climate in today's schools.

Collaboration with other school professionals is critical in implementing a career intervention program. Although ASCA has suggested an ideal counselor–student ratio as 1:250, many counselors work with a larger counselor–student ratio. One counselor cannot accomplish all the goals and objectives necessary for a successful career intervention program. Therefore, incorporating teachers, students, parents, and community participants becomes inevitable.

The Career Development Research Team of the National Research Center for Career and Technical Education established a comprehensive list of career intervention programs that occur in secondary schools and created a taxonomy of the identified interventions (Dykeman et al., 2001). The creation of the taxonomy (see Table 32.1) helps to standardize the career guidance in terms of both content and structure; it provides school counselors with a parsimonious framework to judge where their school's career guidance efforts are underdeveloped. The career intervention taxonomy as described by Dykeman et al. can be classified into four major taxons:

Taxon 1: Work-Based Interventions
Work-based interventions are those activities that promote career development through providing students with meaningful interactions at a job site(s).

Taxon 2: Advising Interventions
Career advising interventions are designed to provide direction and help students plan for both the present and the future. The majority of advising takes place in late middle school through high school. It is usually done on a more individual basis, tailored fit to the specific student's strengths.

Taxon 3: Introductory Interventions
Introductory interventions have the purpose of awakening a student's interests for both personal and professional growth. This intervention is generally short in duration and is a "snapshot" of experiences and/or information. These usually prepare students for a follow-up of information that has more depth. Introductory interventions are tied closely with curriculum-based interventions, with the main differences being in the amount of time and detail.

Taxon 4: Curriculum-Based Interventions
Curriculum interventions are designed to aid students in learning academic knowledge and career skills that are relevant to the work world. They are generally longer in duration and encompass a large variety of presentation avenues. This taxon can be transferred through a variety of people; for example, school counselors, classroom teachers, presenters, and community members.

The following sections review research related to career development of school-aged populations and career interventions. The career developmental needs, counselor's role, and effective career intervention are each described at elementary, middle, high school, and college levels.

Career Development in School Settings

Elementary School

The specific career development competencies identified as appropriate for elementary school children are

- Self-knowledge
  - Describe positive characteristics about self
  - Demonstrate skill in resolving conflicts
  - Identify ways to express and deal with feelings
- Educational and occupational exploration
  - Awareness of the benefits of educational achievement
  - Awareness of the relationship between work and learning
  - Skills to understand and use career information
  - Awareness of the importance of personal responsibility and good work habits
  - Awareness of how work relates to the needs and functions of society
- Career planning
  - Understanding how to make decisions
  - Awareness of interrelationship of life roles
  - Awareness of different occupations and changing male/female roles
  - Awareness of the career planning process

Characteristics and Developmental Needs. According to Super (1990), elementary school children are typically at the *growth* stage of their career development, which is characterized by fantasy, formation of career interests, and capacity. Gottfredson (1981) described this stage as one in which children begin to develop a sense of sex role (ages 6–8) and become aware of social class in the work world (ages 9–13). Children of elementary school age are perhaps the most moldable because they are generalists in the sense that they are typically open to a broad range of stim-

uli and learning modes (Herr, Cramer, & Niles, 2004). Yet, they are also vulnerable to any inaccurate, stereotyped, and distorted information to which they are exposed. The sexual stereotyping of occupations begins at a young age. For example, Pierce (1993) investigated fiction in teen magazines and concluded that girls are portrayed as dependent rather than independent and that occupations are typically segregated by gender. Using qualitative research methods to study elementary school children, Adler, Kless, and Adler (1992) concluded that boys achieve popularity based on their toughness and athletic abilities, whereas girls achieved high status based on their physical appearance, social skills, and academic success.

Gender and Racial/Ethnic Differences. Gender differences in perception of occupations are well documented. Many studies concern children's gender-stereotyped beliefs and knowledge about occupations, often reporting a high degree of sex-typing along traditional occupational gender lines (McMahon & Patton, 1997; Trice, 2000). Children develop a belief that certain occupations are not appropriate for them because of their gender. Boys generally perceive more opportunities in the world of work than girls do. At the same time, boys tend to have more rigid sex-based preferences than girls do (Awender & Wearne, 1990).

Racial stereotyping could also play a profound role in children's career development. Restricted choice is a phenomenon seen in the career choices of minority students. For example, it is well known that African Americans are underrepresented in enterprising and investigative types of occupations and overrepresented in realistic and social types of occupations as measured by Holland's (1997) RIASEC typology. Asian Americans, on the other hand, are constricted to science and engineering types of occupational choice. In a study conducted by Leong and Hayes (1990), for example, male Asian Americans were seen as successful engineers, computer scientists, and mathematicians, but not as successful insurance salespersons.

Students in this stage could easily and prematurely constrict their career choices based on perceived prestige or sex-type factors. Research has indicated a widening gap in occupational aspirations across race, sex, and socioeconomic status with advancing age, suggesting that as children age, they become more aware of career barriers in relation to their sex, race, and socioeconomic status (Hartung, Porfeli, & Vondracek, 2005).

Elementary school years set the tone for developing the skills, knowledge, and attitudes necessary for our children to become successful and productive adults. It is critical that children at this stage be exposed to a wider variety and range of options in activities, hobbies, interests, roles, and behaviors. They need to experience sex-fair education, counseling, and curriculum at school (Sundal-Hansen, 1984).

Counselors' Roles. Counselors play a critical role in young pupils' lives. Historically, elementary school counselors have been defined by the three C's: **C**ounseling, **C**oordinating, and **C**onsulting. How much each of these is used depends on the needs and resources that characterize a local setting. The American School Counselor Association described the role of elementary school counselor as one who will

- Implement effective classroom guidance focusing on understanding of self and others; coping strategies, peer relationships, and effective social skills; communication, problem solving, decision making, conflict resolution, and study skills; career awareness and the world of work; substance education and multicultural awareness.
- Provide individual and small group counseling dealing with self-image, self-esteem, personal adjustment, family issues, interpersonal concerns, academic development, and behavior modification.
- Provide assessment by helping students identify their skills, abilities, achievements, and interests through counseling guidance activities and interpretation of standardized tests.
- Develop students' career awareness as a lifelong process of forming basic values, attitudes, and interests regarding their future world of work.
- Coordinate school, community, and business resources, schoolwide guidance-related activities, and extracurricular programs that promote students' personal growth and skill development. (Campbell & Dahir, 1997, p. 69)

Classroom guidance activities. Classroom guidance activities are very common counseling activities in the elementary school setting. School counselors use classroom guidance activities to facilitate career development of young children. For example, Beale (2003) described an innovative classroom guidance activity through which he helped third and fourth graders learn about the importance of teamwork and conflict resolution in a workplace. Herr and colleagues (2004) suggested several classroom guidance activities that may be useful for elementary school students:

- Select a career cluster requiring competence in a particular subject matter, such as math, science, or language and identify occupations related to it.
- Do oral reports on different occupations with the student pretending to be a worker in the report.

- Use ingredients of emotional intelligence as the focus of discussion with students.
- Have students prepare autobiographies and address at least three ways in which their lives are influenced by family, school, and peers.
- Build interest centers around different career clusters or ways to assess self-characteristics.
- Provide listening centers that include individual earphones, recording devices, CD-DVD, tapes, and cassettes dealing with worker interviews, study skills, and topics related to self-understanding.
- Provide reference books or biographies that portray personal decision making.
- Show guidance films on selected topics. (pp. 357–358)

Group activities. Other common counseling activities that are appropriate for elementary school children could be delivered through group activities. Herr and colleagues (2004) provided examples of group activities. Several are highlighted here:

- Using a supply of magazines, have students locate pictures that break down traditional male–female occupational role stereotyping (e.g., male nurse, female physician, male secretary, female truck driver). Discuss.
- Have students keep a log of all examples of occupational stereotyping that they discover while watching TV.
- In a role playing situation, have students break into pairs and role-play an employer who is interviewing an applicant for a job. The interviewer wants to know why the person wants the job—besides the money.
- Invite resource persons to discuss how personal characteristics contribute to daily functioning or ask them to discuss their vocational history in relation to what they now do.
- Develop and organize lists of resource speakers and field trips to observe the workers' roles in various occupations.
- Have students design games to play about different approaches to decision making, career options, or other life situations.
- Have students design creative drama skits that deal with self-concept, values, making choices, and other pertinent topics.
- Using pictures of people at work, have students distinguish between those involving the production of goods and those in the performance of services.
- Have students match pictures of tools and what they are used for. Discuss the use of tools for different purposes in school and in work. (pp. 358–360)

Research. Empirical studies on children's career development are sparse. Although counselors seek to advance students' career development across all grade levels, relatively few career development activities are offered in elementary school settings. Researchers pay less attention to the career development of young children, even though research suggests that tentative career aspiration and college plans begin emerging in elementary school (Trice & King, 1991). Infusion of career development into curriculum has been proven effective in the elementary school setting. For example, in an empirical study, McMahon, Gillies, and Carroll (2000) investigated the effect of career education on elementary students' perceptions of the relationship between school and occupations. Findings clearly suggested that students were able to link school-based learning with jobs that they were interested in pursuing.

Middle School

Characteristics and Developmental Needs. According to Super (1990), middle school students are in the beginning stages of *exploration*. While some preteens begin to form tentative career choices, typical students are not ready to commit to career choices. This age period is also described by Gottfredson (1981) as a period of orientation to the internal, unique self and specification of career aspirations. Developmentally, middle school students begin cognitive and moral processing, and many school activities play a role in shaping their identity development. For example, ability becomes an important determination of group membership, and career aspirations are tested in novel experiences such as extracurricular activities and part-time jobs (Herr et al., 2004). These identity formation processes in middle school ideally include increased exploration in relation to career development (Akos, Konold, & Niles, 2004). The needs of middle school students are well defined by NOICC:

- Self-knowledge
  - Knowledge of influence of a positive self-concept
  - Skills to interact with others
  - Knowledge of the importance of growth and change
- Educational and occupational exploration
  - Knowledge of benefits of educational achievement to career opportunities
  - Understanding of the relationship between work and learning
  - Skills to locate, understand, and use career information
  - Knowledge of skills necessary to seek and obtain jobs

    - Understanding of how work relates to the needs and functions of the economy and society
- Career planning
    - Skills to make decisions
    - Knowledge of interrelationships of life roles
    - Knowledge of different occupations and changing male/female roles
    - Understanding of the process of career planning

The primary focus of career development during middle school is on exploration. Students need to explore by learning more about self—their interests, skills, and values. Career development tasks for students in middle school should also continue the task of developing students' self-awareness, which began in elementary school.

Guidance activities directed at junior high school students had the largest effect sizes, indicating that guidance efforts may be most effective with preteen aged (rather than high school or college) students (Oliver & Spokane, 1988). Career interventions that assist students with the assessment of their personal aptitudes, abilities, and interests are especially helpful.

Middle school students also need to explore the world of work. Hartung et al. (2005) reviewed literature on child vocational development and concluded that preteens explore the world of work much earlier than theorists and researchers have typically assumed. Teaching students how to locate educational and career information and how to interpret and use it could pave the way for the development of subsequent career tasks.

Counselor's Roles and Career Interventions. To help guide students in their exploration, counselors can administer career assessments. Career decision making is a complex process by which the decision makers are required to process information about themselves and information about the world of work (Jepsen, 1984). Information about self including interests, skills, and values is particularly useful for career exploration purposes and can be assessed formally and informally. Counselors can use individual counseling, group activities, or classroom guidance activities to help students better understand themselves. For example, the counselor could help students identify "transferable skills" in a group activity. Students could complete a worksheet containing a list of transferable skills. They then could identify situations in which skills are used in school and also situations when skills could be used in a career.

Counselors could also conduct a formal assessment using interest inventories. For example, the Career Decision-Making System developed by Harrington and O'Shea (1992) has color-coded interest clusters that are especially user-friendly for middle school students.

Another effective approach could be to use career portfolios as a counseling intervention for the middle school students. Portfolios are a way of assessing the skills students have mastered and the progress students have made toward educational and vocational planning. Counselors could then review a portfolio with students to help them evaluate where they were, where they are now, and where they want to be. An example of a portfolio is shown in Figure 32.1.

Research. Research has suggested that middle school students, in general, are lacking understanding of how school relates to the real world (Schultheiss, Palma, & Manzi, 2005). They are also lacking awareness of the knowledge and skills needed for success in the work world (Akos et al., 2004; Johnson, 2000). Many young adolescents have sex-stereotyped views of occupations and often have already limited their aspirations (McDonald & Jessell, 1992). They have difficulty seeing a connection between what they learn in school and future careers, and they often lack guidance in selecting courses that lay the groundwork for their high school and post–high school plans.

Connecting students' learning in school with the world of work is important especially for middle school students. Career counseling and education are critical components in a comprehensive counseling program in school settings. Research has shown students are more likely to stay in school and engaged in learning when they see the relevance of their course work (Lapan et al., 2001). This research examined the relationships between statewide implementation of comprehensive guidance programs and indicators of safety and success for seventh graders. After accounting for differences between schools due to socioeconomic status and enrollment size, students attending middle schools with more fully implemented comprehensive programs reported believing that their education was more relevant and important for their futures.

Using a nationally representative sample, Mau (2003) investigated persistence of career aspirations in science and engineering professional careers (SE) as a function of race and gender. A nationally representative sample of eighth graders who initially aspired to science and engineering careers and persisted for six years in the same career aspirations were identified. Results showed that males are more likely than females to persist in SE career aspirations. Academic proficiency and math self-efficacy were among the strongest predictors of persistence in SE careers. Seymour (1995) argued that females may be concerned that by being accepted by their male peers, they may lose their "femininity." They may also have to deal with discrimination and hostility from some faculty and male students (Stafford, 1991). For adolescent women, the

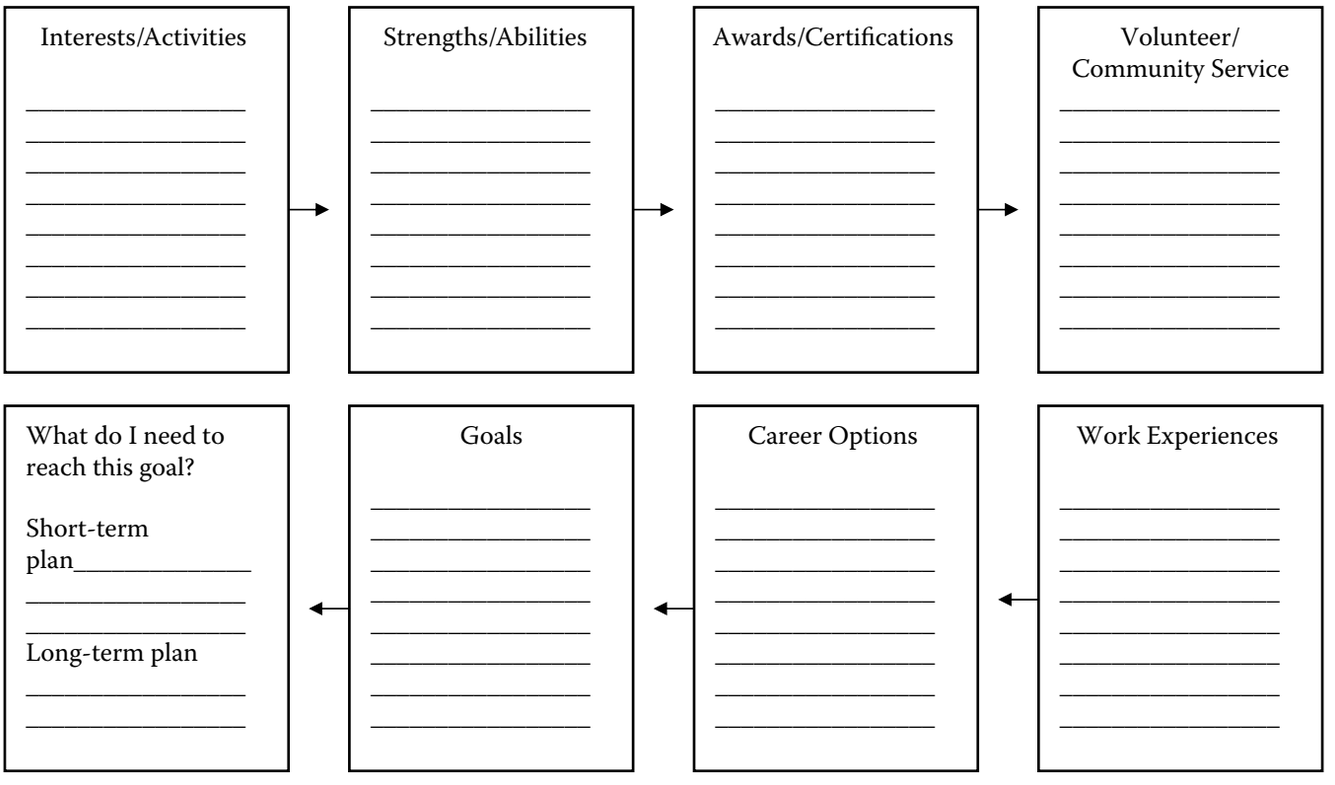
9th GRADE



pressures of trying to balance current and future gender relations in an environment that challenges conventional norms for women creates additional tensions and contradictions (McKinnon & Ahola-Sidaway, 1995). Other factors, such as lower teacher expectations (Anderson, 1992) and lack of role models (Dryler, 1998; Nauta & Kokaly, 2001) may also explain the loss of women in the pipeline. Career interventions that expose students to female role models in engineering and science may inspire students to pursue SE careers. It would appear that programs designed to encourage adolescent women to enroll in SE-related courses need to be sensitive to the intimidation and subtle pressures they may face. Bright young women and underrepresented minorities simply cannot be recruited into the SE pipeline without continued support and encouragement. Informal support groups may be helpful in addressing problems that young women and ethnic minority students enrolled in nontraditional programs or course work may face. Efforts to strengthen support systems and lessen barriers may better enable students to persist toward their career goals (R. W. Lent & Brown, 1996).

Given the importance of self-efficacy, interventions developed to build confidence and increase self-understanding of minority and female students are crucial. Betz (1992) suggested the following interventions to increase efficacy expectations: structuring performance accomplishments, observational learning, anxiety management, and verbal persuasion and encouragement. Given the unique contribution of gender and race factors in predicting SE persistence, counselors need to take a proactive approach in tailoring developmentally appropriate and culturally sensitive career interventions for individuals from diverse cultural backgrounds (Mau, 2003).

These findings suggest that middle school students need to learn to think about the future; recognize their responsibility for educational planning; broaden their aspirations beyond the stereotypes of gender, ethnicity, and socioeconomic level; develop and maintain self-esteem; develop cognitive complexity (essential for the knowledge work of the future); have parental support for career choices; understand how school relates to future life roles; and recognize the broad scope of work in the 21st century.

High School

Characteristics and Needs. As students transition to high school, they focus more directly on the task of identifying occupational preferences and clarifying career choices. High school students are developmentally characterized by Super (1990) as being in the exploration stage of their career development. The tasks of crystallizing, specifying, and implementing tentative career choices occur during this stage. Many individuals during this stage crystallize their daydreams into a publicly recognized vocational identity. Through more focused effort, they eventually complete the task of specifying an occupational choice by translating privately experienced occupational self-concept into educational/vocational choices (Super, Savickas, & Super, 1996). The needs of high school students are well defined by NOICC (1992):

- Self-knowledge
  - Understanding of the influence of positive self-concept
  - Skills to interact positively with others
  - Understanding of the impact of growth and development
- Educational and occupational exploration
  - Understanding of the relationship between educational achievement and career planning
  - Understanding of the need for positive attitudes toward work and learning
  - Skills to locate, evaluate, and interpret career information
  - Skills to prepare to seek, obtain, maintain, and change jobs
  - Understanding of how societal needs and functions influence the nature and structure of work
- Career planning
  - Skills to make decisions
  - Understanding of the interrelationship of life roles
  - Understanding of the continuous changes in male and female roles
  - Skills in career planning

Counselors' Roles and Career Interventions. The immediate concern of high school students upon graduation is whether to participate in the work force or go to college. They must decide earlier in school whether to take a vocational track, a college preparatory track, or pursue other options such as an apprenticeship training program. Students need to be aware of the array of postsecondary school options—college, other postsecondary education, work, nonwork, military, or government service. Counselors could help students examine the advantages and disadvantages of each option, including those occupations that do not require a college degree. Many good jobs do not require a college degree. However, the labor market continues to drastically increase its skill demands, especially in the technology domain, and college graduates also generally have earning advantages (Niles & Harris-Bowlsbey, 2005). Thus, helping students developing a long-term goal to achieve some form of college degree becomes essential.

A recent National Center for Educational Statistics (NCES) report (Parsad, Alexander, Farris, & Hudson, 2003) on high school guidance counseling indicated that when asked about the activities that take up more than 20% of guidance staff's time, the most often cited activity was assisting students in their choices and scheduling of high school courses. The second most commonly cited activity was postsecondary admissions and selections, and one third of the schools said that dealing with student attendance and discipline took up more than 20% of their guidance staff's time. While it appears that high school counselors are not spending much time directly engaged in assisting students with career planning, the NCES survey shows that guidance programs are generally equipped with tools students can use on their own. The vast majority of schools stock computerized and noncomputerized career information sources and college catalogues, as well as conduct testing for career planning.

Tracey, Robins, and Hofsess (2005) suggested that high school years are a time of focus for career interventions because students' career interests begin to stabilize. This study suggested that career development systematically increases with age during the high school years. The major component of career development involves discussing jobs with parents, talking with workers in certain jobs, attending job fairs, and taking tours of local businesses. The major career development emphasis in high school needs to be on the specific and comprehensive planning of immediate, intermediate, and future educational and vocational choices after high school (Herr et al., 2004). The examples of comprehensive sequential career intervention activities at the high school level differ from those at the elementary or middle school level. In many parts of the United States, large school districts have created a sequential program of career intervention that blends career guidance and career education. For example, South High School in USD 259 Wichita Public Schools, Kansas, created a career development program that is committed to allowing opportunities for self and career exploration, as well as the development of communication and workplace skills that will help students become productive and responsible citizens. The comprehensive program, aligned with National Career Development Guidelines and reviewed with National Standards for School Counseling Programs (American School Counselor Association, 2003), consists of (a) career portfolio (b) special career planning activities, (c) a career resource center, and (d) grade-level activities. Examples of grade level activities are

1. Freshmen—English 1
   - Goal Setting
     - Portfolio Insert Card
     - Writing Activity
   - Job Seeking and Keeping
     - Teamwork Activity
2. Sophomores—English 2
   - Goal Setting
   - Portfolio Insert Card

   - Goal Setting
     - SMART Formula and Career Timeline
   - Problem-solving in the Workplace
     - Six-step Process
     - Teamwork Activity
4. Seniors—English
   - Goal Setting
     - Portfolio Insert Cards
   - Resumes and Interviewing
     - Use of Career Resource Center
     - Provide CD-Roms

Research. One major role of high school counselors is to advise students in class scheduling, college preparation, and post–high school selection of work or school. Advising can take many forms and functions and is often delivered in the form of individual or group guidance. Some forms of advising interventions include academic planning, career maps, interest assessments, interviewing information, career libraries or resource centers, college admissions testing, and job hunting guidance (Dykeman et al., 2001). Dykeman and his colleagues (2003) found through a student opinion poll that students who were advised and given directions for planning had increased motivation in mathematics. Peterson, Long, and Billops (1999) found that eighth graders who received assistance with course planning were more able to understand the importance of their class choices. Helping students set goals for the future may increase academic efforts and performance because students have more direction and motivation for their academic work.

Studies (e.g., Mau, Hitchcock, & Calvert, 1998) have shown that counselors are the last people from whom students seek help. They tend to seek help from their peers, parents, or teachers first. Counselors, therefore, could act as consultants, trainers, or program coordinators to involve

parents, teachers, students, and community experts in career intervention programs. Formal programs can be developed to assist parents of minority students in communicating to teachers and counselors their academic expectations for their sons and daughters (Atkinson, Morten, & Sue, 1993). These programs also can be utilized by counselors to encourage parents to view educational choices in a realistic fashion, to help parents communicate these views to their children, and to help parents understand the curricular options and consequences of various academic choices (Commission on Precollege Guidance and Counseling, 1986).

Minority students are underrepresented in higher education. A national survey has indicated that Hispanic and African American high school students have lower college aspirations than White or Asian American high school students (Mau & Bikos, 2000). Programs that target minority students in exploring higher education options are especially appropriate. Findings based on a nationally representative high school student sample indicated that counseling services are not equally available to public school students (Lee & Ekstrom, 1987). Similarly, the final report of the Commission on Precollege Guidance and Counseling (1986) also indicated that many students have either little or no access to counselors at this critical time. As suggested by Lee and Ekstrom, counselors may be so busy with paperwork or other responsibilities that individual counseling and advising situations are rare. High student-to-counselor ratios also may limit the availability of counseling or advising services (Boyer, 1983). Students of minority background are less likely to access guidance counseling for making important educational and vocational decisions. Nevertheless, counselors need to be aware of cultural barriers that may inhibit minority students from seeking counseling help, such as feelings of shame (Mau & Jepsen, 1988), biased nature of the services (Sue & Sue, 2003) differences in coping strategies (Mau & Jepsen, 1990; Yeh & Inose, 2002), and differences in counseling expectancies (Altmaier & Rapaport, 1984). Considering, the high student-to-counselor ratios, computer-assisted career intervention systems may be implemented to ease the heavy workload of counselors. However, computer-based intervention shouldn't replace the counselor's work. Computer interventions with the counselor's follow up produce the most effective outcomes. Counselors need to be aware of the effective use of computer-assisted guidance systems (Sampson, 1994). Because students prefer to seek help from their peers, counselors may need to use approaches that are less threatening to students (Mau, 1995). Programs such as "Natural Helpers" (Comprehensive Health Education Foundation, 1997), which utilize informal or natural support systems, may be implemented.

Enhancing career self-efficacy of students is an important component of career interventions for high school students. A number of studies have investigated the effects of various interventions on career self-efficacy. O'Brien and her colleagues (2000) conducted a small-group career exploration and planning for Upward Bound students. Results indicated that students who received the career intervention exhibited significantly higher levels of career decision-making self-efficacy than did the students in the control group. McWhirter, Rasheed, and Crothers (2000) investigated the impact of a 9-week career education class on the career decision-making self-efficacy, vocational skill efficacy, and perceived educational barriers, outcome expectations, and educational plans among a sample of 166 high school students. Results suggested that students in the course as compared with students in the control group, showed increases in career decision-making self-efficacy and in vocational skill self-efficacy, and a short-term gain in outcome expectations.

College

Characteristics and Needs. Late adolescents and young adults are involved in multiple developmental challenges and transitions (Schultheiss, 2000). One of the most important career developmental tasks for young adults attending college is making a successful transition from school to work. For many college students, acquiring a satisfying career is the main reason for pursuing a college degree. National statistics have indicated that more than half of high school graduates attend some form of college and about 50% of students who enter colleges and universities graduate within six years (Gray & Herr, 2000). A Gallup survey sponsored by the National Career Development Association (NCDA) showed that 60% of college graduates would try to get more information about job and career options if they were starting over (NCDA, 1999). The survey also indicated that more ethnic minorities than Whites and more traditional (aged 18–25) than nontraditional students (aged 26 and over) reported a greater need for career assistance.

Herr and colleagues (2004) have identified segments of the college population that require special counseling support. Among these subpopulations, visible minorities include students such as physically challenged persons and ethnic minorities. Examples of less visible minority groups are students with gay, lesbian, and bisexual orientations. The needs of these subpopulations extend beyond "normal" boundaries because they may encounter internal barriers (e.g., low self-efficacy, financial difficulties) and external barriers such as prejudice and discrimination. Herr et al. also pointed out that international, adult/nontraditional,

gifted, and liberal arts students also have unique concerns that require special attention.

This increased diversity suggests that career development interventions in colleges and universities must be comprehensive and planned systematically to meet the diverse needs of students today. The effectiveness of career counseling practices depends largely on the manner in which the unique needs of diverse populations are recognized and addressed. As with K–12, the National Career Development Guidelines (NOICC, 1992) also identified adult-level competencies:

- Self-knowledge
  - The skills to maintain a positive self-concept
  - The skills to maintain effective behaviors
  - Understanding of developmental changes and transitions
- Educational and occupational exploration
  - The skills to enter and participate in educational training
  - The skills to participate in work and lifelong learning
  - The skills to locate, evaluate, and interpret career information
  - The skills to prepare to seek, obtain, maintain, and change jobs
  - An understanding of how the needs and functions of society influence the nature and structure of work
- Career planning
  - The skills to make decisions
  - Understanding of the impact of work on individual and family life
  - Understanding of the continuing changes in male/female roles
  - The skills required to make career transitions

Counseling Intervention. The actual competency to be developed, the process, and the specific activities to be used will vary based on the nature and philosophy of the institution. There are several career intervention models for college students that can be used to address the competencies identified by NOICC. For example, Reardon (1996) described a comprehensive career intervention model used at Florida State University. The model is a curricular-based career information service model that consists of five modules. The focuses of this career service model are on providing students with an introduction to the service, helping students engage in self-assessment and locate career information, and helping students match majors and jobs. Isaacson and Brown (2000) suggested the following approach:

1. Outreach
   a. Career seminars in housing units
   b. Informal rap sessions in housing units to establish contact
   c. Activities designed for special groups (e.g., international students) delivered at their meeting
   d. Mentoring program using alumni or upper classmen
   e. Parental involvement such as career development seminars
2. Classroom instruction
   a. Required classes for credit
   b. Optional classes for credit
   c. Noncredit, short-term classes
   d. Employability skills training classes
   e. Unit in regular classes dealing with careers
3. Counseling
   a. Individual career counseling
   b. Group career counseling
   c. Employability groups
   d. Special programs for alumni such as group counseling activities
   e. Support groups for job hunters
4. Assessment
   a. Screening examinations given at entry to focus on career/decision making
   b. Ongoing assessment offered to students in counseling/career planning and placement center
   c. Assessment used as part of career counseling
   d. Computer-assisted services
   e. Self-direct assessment (e.g., self-directed search)
   f. Needs assessment
5. Information
   a. Orientation session/information
   b. Catalogs
   c. Advising information/careers
   d. Career information center
   e. Articles in student newspapers
   f. Computer-assisted systems
   g. Handouts that relate educational programs to career opportunities
   h. Alumni newsletters
6. Placement
   a. Regular job placement
   b. Job fairs to link employers and workers
7. Work experience
   a. Internship program
   b. Placement for part-time work
   c. Cooperative educational/work programs
   d. Work–study programs
8. Consultation
   a. With faculty advisors to make them aware of education–career connection; needs of certain students
   b. With residence hall assistants and directors to provide assistance

c. With instructors who wish to infuse more career information
d. With club/social activities advisors to suggest career related activities

9. Referral
   a. To workers in the community for career information
   b. To mental health professionals to get assistance with personal problems blocking career related decisions.

Herr et al. (2004) suggested that career interventions should proceed in an orderly, systematic fashion to meet the unique needs of students at different points during college life. For example, during the freshman year, information concerning curriculum and career implications in different majors is especially helpful. For sophomores, assistance in exploration of an academic major is very much needed. For juniors, engagement in internships, cooperative education, or job search skill training is especially appropriate. During the senior year, assistance with access to world of work, resume writing, and mock interviewing to facilitate school-to-work transitions are critical.

Course-based career interventions. A career planning course is one of the most common programs offered in college and university settings. Folsom and Reardon (2003) documented the efficacy of course-based career interventions and reported the results of their examination of 46 studies of course-related outcomes published from 1976 to 2001. Their report indicated that a majority of these course-based interventions produced positive outcomes such as career decision-making skills, career decidedness, career maturity, persistence, retention, and satisfaction.

Savickas (1990) also designed and tested a career exploration course consisting of the following components: (a) become involved now, (b) explore your future, (c) choose based on how things look to you, (d) control your future, (e) work, a problem or opportunity, (f) view work positively, (g) conceptualize career choices, (h) clear up career choice misconceptions, (i) base your choice on yourself, and (j) four aspects of self as choice bases. He found students enrolled in this course were more oriented to a future time perspective. S. Solberg et al. (1998) used a curriculum-based college-age intervention called the Adaptive Success Identity Plan (ASIP). It measured the construct of success identity as the core guiding factor in college success. The study showed that students who received the ASIP curriculum were more likely to define their role in college around the success identity construct. Students were given a list of questions that were coded into four units of thought. After the ASIP interventions, students were more likely to broaden their "success vocabulary" from self-determination to words such as *self-efficacy*, *social integration*, *faculty integration*, and *outcome expectations*. This led to the conclusion that ASIP curriculum caused changes in student perceptions, and these results might generalize to other settings.

Robbins and Smith (1993) evaluated the effectiveness of an enhancement program for students entering college**.** The program is designed to help college students just entering school adjust quickly and smoothly. This class consisted of 10 weeks of curriculum including study skills, campus resources, visiting the career planning office, and instruction on how to have positive relationships with professors. After 10 weeks, results of the class were assessed. Robbins and Smith found that the class did broaden and quicken the students' knowledge base about college. Students felt more satisfied with their college experience after participating in the class. One negative knowledge point they found was a drop in student knowledge about a specific acquired field. This might mean the students had a lack of focused interest during their first college semester.

Computer-assisted career guidance system (CACGS). Most of the CACG systems are designed to assist individuals in learning about themselves (i.e., career assessment approach), or learning about the world of work, (i.e., career exploration approach). CACGS are often coupled with counseling interventions and various print and media-based support resources and are used within an organization to assist individuals in making current career decisions as well as to improve their capacity to make effective career decisions in the future. About 10.6% of college students reported that they had used one of the CACGS (Hoyt & Lester, 1995). College counselors and professional academic advisors have large client loads and heavy demands on their time. Therefore, students' requests for more personal assistance with academic planning may not be met by individual or group counseling, simply because the professionals do not have enough time or there are other students or other problems considered more pressing. CACG systems come in many forms. Studies in general have shown the CACGS to have a positive impact on career development of college students. For example, the CACGS has increased students' career self-efficacy and career decidedness (Fukuyama, Probert, Nevill, & Metzler, 1988), career decision commitment (Pinder & Fizgerald, 1984), and vocational identity and exploratory behavior (Mau, 1999).

Career fairs and internships. Career centers help college students better connect school to the community. Programs such as "Way with Words" help increase civic responsibility in students (Flores et al., 2002). The more college students connect with the community, the more efficient and prepared they will be to enter the workforce.

Deciding on a major field of study is one of the most important tasks for college students. Elliot (1988) described a program that helps students with choosing a college major. Undecided students along with faculty representatives of various academic programs were invited to attend an evening program in which students and faculty could interact about major areas of study. The program was well received by the participants.

Research. The perception of career related barriers and decision-making difficulties plays a significant role in the career development of women and ethnic minorities (W. L. Lent, Brown, & Hackett, 1994). Studies have shown that women and ethnic minorities perceived more career related barriers than did White Americans (Luzzo & McWhirter, 2001). In a cross-national study, Mau (2001) found that Taiwanese college students perceived more career decision-making difficulties than American college students. He also found that the clusters of difficulty had a different impact on career indecision depending on students' nationalities. Parallel to this study, Mau (2004) also compared the racial differences in career decision-making difficulties among college students. Results showed that Asian American students perceived significantly more difficulties in career decision making than other groups, whereas White American students perceived the fewest difficulties compared with other groups.

While minority students are more likely to experience decision-making difficulties, they do not always seek professional counseling help. A national survey on career services in postsecondary education has indicated that about 1 out of every 2 students has never used career counseling services (Mau & Fernandes, 2001), with Hispanic students the least likely to utilize career counseling services. Aggressive outreach efforts that target this group and that are tailored to increase utilization of services should be created. Counseling professionals need to take a proactive role in reaching this population. For example, Flores and Spanierman (1998) suggested that flyers be posted in the community at establishments that serve these targeted students. Providing information and/or making a presentation at a Hispanic American Student Association meeting may be more appropriate than waiting for students to seek counseling help at the center.

Consideration should be given to taking programs and services to locations where various subpopulations of students naturally congregate (Bishop, 1990). The ability to reach out effectively to minority students will be increasingly important, and service delivery systems must be adapted in order to accommodate such populations. Counseling professionals need to be more sensitive to potential barriers that may inhibit those who underutilize these services in seeking professional help. Needs assessments can be conducted to examine the unique concerns of this diverse population (Davidson, Heppner, & Johnston, 2001). The type of services provided through the career center should be appropriate to the needs of all students including the culturally diverse. When professionals acknowledge the unique factors of these students and their cultural beliefs, attitudes and types of career concerns, the students may be more likely to return for continued services.

Future Directions

Career interventions have generally been shown to have positive effects. Baker and Popowicz (1983) reported an overall effect size of .50 for career education studies, and Spokane and Oliver (1983) obtained an average effect size of .85 over all types of career interventions. Oliver and Spokane (1988) extended their meta-analyses and reported a similar overall effect size. They also reported effect size by age group with the middle school age having the biggest effect size (1.28), then, high school age (1.02), and college age having the smallest effect size (.85). In their meta-analyses, only one study involved the elementary school age population, which had an effect size of –.001. It is therefore not meaningful to evaluate the effectiveness of career intervention for this population based on one single study.

It is quite disturbing to find the lack of empirical studies investigating the effectiveness of career interventions with elementary school and middle school students. Whiston, Brecheisen, and Stephens (2003) documented that almost 50% of the studies conducted in the last 50 years involved college populations. There was only one experimental study on elementary-aged children conducted between 1983 and 1995 (Whiston, Sexton, & Lasoff, 1998).

Despite the importance of career developmental tasks as described by Super (1990), little systematic investigation has been conducted to confirm theoretical assumptions evident in children's models of life span career development. Research focusing on contributing conceptual knowledge of childhood career development is urgently needed to inform early career interventions and help children develop a meaningful understanding of the relevance of school-based learning to their future careers (Johnson, 2000).

Whereas college students received the most research attention, the effect size generated from those outcome studies appears to be smaller than other age groups. It is unclear if this is because college students face different types of career problems or they are less amenable than younger age groups. Further research may be able to clarify this issue.

Meta-analysis studies over the last 2 decades (e.g., Brown & Ryan Krane, 2000; Brown et al., 2003; Oliver & Spokane, 1988; Spokane & Oliver, 1983; Whiston et al., 1998) have continued to indicate that career interventions in general are effective. However, career interventions are not a homogeneous group producing a homogeneous effect. Previous meta-analyses have begun to analyze the effectiveness by treatment types, outcome measures, and participant's characteristics. Nevertheless, none of the meta-analysis studies have examined the treatment impact on racial/ethnic groups.

Unfortunately, most school-based studies do not have rigorous experimental control. It is extremely difficult to conduct experimental studies involving a control group in the school setting. However, school outcome researchers should consider the use of wait-list control groups that are commonly used in general counseling outcome research (Whiston et al., 1998). Research also needs to examine longitudinal effects of career interventions. Most of the studies are based on one-shot, short-term interventions. Results generated from these studies tend to be artificial and tentative. One pathway for future research involves responding to recent calls for research on life-span vocational development that uses truly longitudinal designs (Savickas, 2002). National databases sponsored by the Department of Education, such as the Early Childhood Longitudinal Study and the National Educational Longitudinal Study provide researchers with ample research topics examining the educational/vocational behaviors of school-aged students.

More recent meta-analyses (i.e., Brown & Ryan Krane, 2000; Brown et al., 2003) of career choice intervention literature have identified five critical ingredients involving any effective career intervention. The five critical ingredients are (a) workbooks and written exercises that require participants to write their goals and future plans; (b) individualized interpretations and feedback that provide participants individualized feedback regarding test results, goals, and future plans; (c) in-session occupational information explorations that provide opportunities to gather information on the world of work or specific career options; (d) modeling through counselor self-disclosure, guest speakers, and interaction with appropriate models; and (e) support-building that facilitates participants to gain support from their social network. Based on these findings, Brown et al. have made specific suggestions and hypotheses on how to improve career interventions.

Career counseling must take into consideration students' racial/ethnic backgrounds. A recent meta-analysis of race/ethnicity differences in career development suggested that significant differences exist among racial/ethnic groups in regard to the perception of career related opportunities and barriers (Fouad & Byars-Winston, 2005). It is important that a discussion of opportunities and barriers be incorporated into career interventions with minority students. Much of the existing research has been conducted with middle-class suburban youth, limiting the knowledge of more diverse groups in terms of socioeconomic status (Schultheiss et al., 2005).

It is predicted that by 2020, the majority of school-aged children in the United States will be from racial/ethnic minority groups, and persons of color will constitute a numerical majority sometime between 2030 and 2050 (Sue & Sue, 2003). Career counseling in the 21st century is called to shift paradigms when responding to the changing population and the standards-focused climate in our schools today. Traditional approaches to counseling that emphasize an individual-focused, client-centered, self-actualization approach may be insufficient or counter-productive in working with racial/ethnic minority students. Pedersen (2000) noted that society and culture in the United States is based on the concept of individualism and that competition for status, recognition, and achievement form the basis for Western tradition. Basic to this individualistic assumption is that the individual has the primary responsibility for his or her own actions. Independence and autonomy are highly valued, and one should be internally directed and controlled (Sue & Sue, 2003). However, from a cross-cultural perspective, the validity of these assumptions has yet to be verified. For example, the meaning of "self" varies across cultures. Individuals from a collective-oriented culture may conceive of self as interdependent, whereas persons from individualistic cultures may view the self as independent. For the latter, career decision making may be an individual matter, while for the former, career decision making may be a familial matter based on group interests, values, and needs. Leong and Brown (1995) strongly suggested that we need to continue to study the cultural validity of Western-based models of career intervention and development with diverse populations.

D. W. Sue and D. Sue (2003) have challenged the notion that "cultural-bounded" values may in fact be barriers to effective multicultural counseling. They suggested that the traditional one-on-one, in-the-office delivery of services must be supplemented by those that are more action oriented and involve roles and activities in natural settings (community, neighborhood, churches, etc.). Counselors need to address the problems that are related to systemic and external forces (e.g., poverty, discrimination, and prejudice) in addition to internal psychological problems. Counselors also should expand their roles to include advocacy of social justice and to be the change agent for student clients when necessary.

In recent years, more and more scholars have begun to reformulate existing counseling theories and approaches, with much attention to issues of cultural context in career development and counseling. For example, Super and col-

leagues (1996) described how the constructs of roles and values make career theories more relevant to women and minorities. Hartung et al. (1998) adapted Super's Career-Development Assessment and Counseling model (C-DAC) for use in career counseling with racial and ethnic minorities. Their extended model includes cultural identity as a core C-DAC element, and culturally sensitive assessments and counseling interventions as part of the assessment and counseling process. Criticizing past research that overly focused on universal dimensions of personality, Leong (1996) proposed an integrative model that proposes the notion that individual clients must exist at three levels—the universal, the group, and the individual. Career counselors using this model recognize that work is universal but its meaning is embedded in a cultural context that shapes and colors its nature and experience. These models have made advances in their effort to improve the process and outcome of career interventions for clients of diverse racial and ethnic minority backgrounds in the school setting (Leong & Tan, 2003).

Career counseling in the school setting has a relatively long history. Substantial research related to career development has been documented. However, there is still not substantial evidence about what works best with clients under what conditions. To achieve this goal, more systematic research that focuses on process and outcome of career counseling is needed (Whiston, 2003).

CREATIVE ARTS COUNSELING IN SCHOOLS: Toward a More Comprehensive Approach

CAROLINE S. CLAUSS-EHLERS

Rutgers, The State University of New Jersey

Creative Arts Counseling in Schools: A Sound Approach With Significant Barriers

Research indicates that creative arts counseling is a highly effective intervention in preschool, elementary, middle school, and high school settings. Fall, Balvanz, Johnson, and Nelson (1999) found that children who received play therapy from school counselors experienced a significant increase in self-efficacy in comparison with the control group of children who did not receive play therapy. Johnson, McLeod, and Fall (1997) examined the efficacy of play therapy in school settings and found the intervention had a significant positive impact. Ray, Armstrong, Warren, and Balkin (2005) investigated elementary school counselor beliefs about creative arts counseling in the schools and learned that they strongly believed in its utility.

Creative arts counseling in schools is a developmentally appropriate intervention that helps children and adolescents cope with challenging situations (Cobia & Henderson, 2003). The provision of creative arts counseling within school systems makes intervention more accessible as youth receive treatment in their natural settings rather than having to be transported to a clinic or private office (Clauss-Ehlers & Weist, 2002). Creative arts counseling also addresses issues associated with stigma. Students may not feel that they are in counseling per se, but rather are engaged in a creative art form that fosters their self-expression, coping skills, and overall well-being.

Despite empirical evidence and a host of substantial benefits, however, very little literature exists about the ways in which creative arts counseling can be implemented more comprehensively in schools (Wengrower, 2001). Lack of knowledge about the counselor's role is one impediment to greater implementation. Within the school setting, the role of the creative arts counselor is often confused with that of the art teacher. The counseling profession itself does not necessarily understand the theoretical concepts, interventions, and unique contributions made by the creative arts approach. To this end, the current author introduces the term *creative arts school counselor* to further identify the role of the counselor who uses creative arts techniques in counseling. It is hoped that this new definition will differentiate the function of the creative arts school counselor from that of art educator, drama teacher, and others. The term *creative arts school counselor* will be used throughout the chapter, including when works by other authors are discussed.

A discussion of creative arts counseling techniques and relevant strategies must first consider the very real barriers associated with implementing creative arts counseling in schools. The culture of creative arts counseling and the culture of school-based education have differences that make it challenging for the two to work together (Wengrower, 2001). The therapy culture, for instance, focuses on the individual or group in contrast to an educational culture that focuses on the class or school. Creative arts counseling emphasizes each child's uniqueness while educational systems focus on common aspects of age level and shared grade, and assume similar learning styles and speed.

The culture of creative arts counseling deals with uncertainty, process, and introspection. In contrast, the educational culture focuses on knowledge of clear concepts, learning rather than doubt or uncertainty, lesson plans, measurable results that are evaluated, and a practical, action-oriented approach to learning. The creative arts school counselor views the therapeutic relationship as a tool to be used in counseling with the child. This differs from the relationship between educator and student that occurs amidst a classroom full of students (Wengrower, 2001).

Wengrower (2001) mentioned other factors that deepen the divide between therapeutic and educational cultures. The concept of parataxic distortion is applicable to those teachers who develop strong relationships with students and subsequently doubt that the creative arts school counselor can do the same (Sullivan, 1954). As a result, the possibility for a collaborative team effort between counselor and teacher becomes difficult, if not impossible, to achieve. The teacher may also be jealous of the creative arts school counselor's work role. The teacher who is in the classroom with students all day, for instance, may feel that the creative arts school counselor does not work as much since she only meets with students on a session-by-session basis (Wengrower).

For creative arts school counselors, an additional barrier is the challenge to maintain a clinical setting (Carroll, 2000). For those schools that have not yet fully integrated creative arts counseling interventions, the creative arts school counselor may find it difficult to acquire consistent office space that ensures ongoing sessions and confidentiality. Educators and administrators may also be concerned about a child being pulled out of class to attend creative arts counseling sessions. If a child leaves the same class once a week for sessions, the result is a 20% absentee rate for a class offered five days a week. After-school sessions may not be an option if the child depends on school transportation to return home. Lack of counseling support from the educational community may mean that the child does not get any counseling or does not attend on a regular basis (e.g., has sessions on a biweekly or monthly basis).

The school calendar itself can act as an impediment to ongoing creative arts counseling (Carroll, 2000). Winter holidays are significant times of stress for many families, yet children are on break during this time and do not have access to counseling within a school setting. Summer breaks last an average of 2 months during which time children do not benefit from school services offered during the academic year. This is unfortunate given that major developmental changes occur during the summer as children prepare for another grade. The lengthy break also interrupts treatment gains for those who have been in counseling, making it difficult to begin where client and creative arts school counselor left off when classes resume.

Another barrier concerns the provision of creative arts counseling to culturally diverse youth in schools. Culturally diverse youth are the fastest growing group in the United States (Porter, 2000). In the year 2000, culturally diverse youth made up almost 30% of the population. An estimated 3,000 immigrants arrive in the United States each day (Martin & Midgeley, 1994).

An evident trend is the young age composition of culturally diverse groups: 35% of Latinos, 33.9% of American Indian/Alaska Natives, 31.9% of Native Hawaiian/Pacific Islanders, 31.4% of Blacks/African Americans, and 24.1% of Asian/Asian Americans are under the age of 18. In comparison, Whites constitute the oldest group with only 22.6% of the total population under 18 years of age (U.S. Bureau of Census, 1996). These findings highlight the reality that we live in a young, diverse society (Clauss-Ehlers, 2003).

Within this cultural context, it is crucial that the creative arts school counselor consider how creative arts counseling can be effective in work with culturally diverse students. Very little attention has been devoted to how creative arts counseling applies to culturally diverse youth in school settings. The importance of cultural factors in the delivery of creative arts counseling needs to be addressed more fully so that the needs of all students are better met.

Despite these barriers, educational settings provide an excellent environment for creative arts counseling. What follows is a discussion about how future research, training, and practice can provide school-based creative arts counseling in a more comprehensive, systemic, developmentally appropriate, and culturally diverse manner. The chapter elaborates on the role of the creative arts school counselor with a focus on strategies associated with a more comprehensive, schoolwide approach. The chapter defines play and reviews creative arts counseling theory, discusses the state of research in creative arts counseling, looks at educational and training requirements for practice, and reviews the key creative arts counseling techniques of play therapy, art therapy, drama therapy, poetry therapy, and sandplay therapy. The review of each technique focuses on relevant definitions, processes, age appropriateness, and application to counseling culturally diverse youth. The conclusion presents an overall theory of creative arts counseling in schools and how communities can work toward a more comprehensive provision of such services.

Theoretical Basis for Creative Arts Counseling in Schools

Theories of play. The debate over how to define and conceptualize play has spanned the course of two centuries (Stagnitti, 2004). Theories of play are generally divided into classical theories and modern theories (Mellou, 1994). Classical theories of play began in the 1800s and examined the purpose of play. The surplus energy theory of play developed by Spencer (1878), for instance, concluded that play did not add anything to a child's development. In Spencer's conception, play simply occurred because children had extra energy. Other tenets of the classical framework believed play gave children a way to relax and was thus part of an evolutionary biological process that weakened primitive instincts (Lazarus, 1883; Hall, 1920).

Modern theories believe that play influences child development (Berlyne, 1960; Erikson, 1985). Play is thought to facilitate exploration and reduce arousal when new scenarios are encountered (Hutt, 1985). Psychodynamic theories of play focus on the emotional component that play brings to the lives of children. These theories state that children can play out their feelings and in so doing, master trauma (Erikson, 1985; Freud, 1961). Sociocultural theories of play examine the socialization process that play provides and how it helps children develop necessary skills for the adult world (Bateson, 1955; Mead, 1934).

The major change seen in the shift from classical to modern theories of play is the importance placed upon the role of play in childhood development. While classical theories saw play as something more functional in the life of a child (i.e., something children engage in to use extra energy), modern theorists take the stance that play has both a functional and therapeutic value as it facilitates the child's emotional, cognitive, and social development (Erikson, 1985; Freud, 1961; Mead, 1934).

Out of these contrasting and evolving theories, contemporary theorists have begun to piece together a definition or, more accurately, to put together characteristics that embody the concept of play. Play is currently described as something that is exploratory; an intrinsically motivated transaction between the individual and the environment; something that is internally motivated, reflects and transcends reality, is controlled by the player, is spontaneous, safe, fun, and concerned with process not product (Stagnitti, 2004).

Similar to modern theories of play, much of the theoretical linkage to creative arts counseling can be traced to both developmental (Piaget, 1962) and psychoanalytic theory (Naumburg, 1950). Piaget had a keen understanding of the different ways in which children and adults understand information. According to Piaget, children between 2 and 7 years of age are at the preoperational stage where they learn language skills and experience both rigid and magical thinking (e.g., the child creates an improbable explanation for something he or she does not understand).

The child experiences the concrete operational stage of development between the ages of 8 and 11 (Piaget, 1962). Here the child is able to organize material and develops the ability to reason logically. The focus of the child's thinking at this time, however, is on physical objects rather than on abstract thoughts or feelings. Creative arts counseling can help children bridge the gap between concrete and abstract thought, provide an opportunity to organize abstract thoughts, and enhance a sense of control and an ability to cope (Ray et al., 2005).

Creative arts therapies are also based on the psychoanalytic tradition in that they involve the expression and interpretation of unconscious material. In art therapy, for instance, children draw pictures and are asked to free associate their meanings. The creative arts school counselor offers interpretations and facilitates goals aimed to "support the ego, foster the development of identity, and promote maturation" (Kahn, 1999, p. 292).

Change in psychoanalytic approaches to creative arts counseling occurs within the context of a dynamic therapeutic relationship between counselor and child. Expression, self-exploration, and understanding are promoted through creativity and play, which is the child's natural way to communicate. Interpretations of play are used to help the child gain awareness of unconscious conflicts.

State of Research in Creative Arts Counseling

Research is an important aspect of a comprehensive approach to school-based creative arts counseling as empirical evidence can support the efficacy and expansion of interventions. Process and outcome research and narrative case study are three current research trends used with children (Carroll, 2000). *Process research* refers to studies that examine factors that emerge during the course of treatment that help children. *Outcome research* examines the child's level of functioning at the end of therapy. *Narrative case study* refers to a narrative written about a particular clinical case that documents the course of treatment and highlights specific aspects of treatment.

Process research. A strength associated with process research is that it explores what fosters a positive counseling process for children. Through empirical examination of those aspects of counseling that most benefit children, counselors have greater awareness of what to replicate and incorporate in their work. Weaknesses associated with process research include extenuating factors such as maturation and the environment that are beyond the researcher's control. As a result, it is difficult to state for certain that specific aspects of the counseling process influenced a positive counseling experience in isolation from extenuating factors.

Outcome research. A key strength associated with outcome research is its more recent focus on methodological issues (Carroll, 2000). Landreth, Homeyer, Glover, and Sweeney (1996), for instance, analyze play therapy studies and provide a comprehensive empirical review of positive counseling outcomes. In their meta-analysis of clinical intervention research with children, Weisz and Weiss (1993) found overwhelmingly positive outcomes.

Weaknesses associated with outcome research often center on problems with design. Outcome research often determines a baseline of functioning among children

before the intervention is delivered (Carroll, 2000). Children are then randomly placed in different research groups and their functioning is remeasured at the end of the study. Problematic with this design strategy is that it measures behavioral symptoms only and does not consider other factors that contribute to changes in functioning.

Measuring outcomes among children also implies that they improve and respond to interventions at the same pace. Some children may respond quickly to an intervention while others may need more time to react (Carroll, 2000). Because the post measures are administered at the same time, diversity of the pace in which each child makes progress is not considered.

Narrative case studies. A key strength of the narrative case study is the ability to pay attention to details that would get lost in a larger study. As a result, this research can demonstrate effective, innovative interventions through documentation of what occurs in treatment. Written accounts that comprise the narrative case study rarely interfere with counseling; thus, the child's therapeutic process is largely uninterrupted (Robson, 1993). The narrative case study approach is also useful for practitioners engaged in research as material is presented in the consulting room rather than an outside environment (Carroll, 2000).

A major weakness associated with narrative case study is the large variability in how different issues are addressed. Some researchers base their narrative on session details while others focus their writing on the therapeutic process in general. This variability makes it difficult to assess the overall contribution and efficacy of narrative case study findings. The uniqueness of each case makes questions of validity, reliability, and generalizability difficult to answer.

Education and Training: The Association for Play Therapy and the American Art Therapy Association

The Association for Play Therapy (APT) and the American Art Therapy Association (AATA) are two professional organizations that provide formal training guidelines for creative arts counseling. Each organization provides a list of approved graduate-level academic training programs (for a comprehensive listing, see Webb, 1999). At the time of this writing, the American Psychological Association (APA) did not offer specific guidelines regarding the practice of creative arts counseling.

The APT provides various types of training for professionals specifically interested in the practice of play therapy. The APT issues credentials for being a Registered Play Therapist (RPT) and Registered Play Therapy-Supervisor (RPT-S) for those who meet their professional standards. Additional training and professional development is provided through the Annual APT International Conference as well as through distance-learning courses in play therapy.

A key organizational activity of the AATA is to examine the quality of training provided by graduate degree programs. The AATA has developed educational standards for master's level graduate programs. Art therapy education courses cover topics such as psychopathology, diagnostic categories, group work, human development, multiculturalism, ethics, research, and assessment. Educational programs will often have additional requirements in counseling theory and practice as many art therapists become licensed as professional counselors. After completion of required master's level course work in art therapy, the student must complete a supervised postgraduate internship. Upon completion of the postgraduate internship, the student is eligible to apply to become an Art Therapist Registered (ATR).

The art therapy education literature acknowledges that its objectives resemble those of the counseling profession, it states that art therapy education is different in three key ways. These differences apply to various types of creative arts counseling (e.g., drama therapy, sandplay therapy). First, materials used in the creative arts counseling process are usually not used in counseling. For instance, a client may use clay, sand, or draw during a creative arts counseling session, mediums that are not traditionally used in counseling.

Art expression is the second major difference and refers to the understanding among art therapists about the significance and meaning of the artwork created by their clients. Part of the creative arts school counselor's task is to be familiar with "normal developmental levels of artistic expression" as well as those that might suggest neurological problems, trauma, or mental illness. Thus, the creative arts counselor must be able to assess the client's artwork from a developmental perspective to make these determinations.

The third major difference involves the nature of the counseling relationship. For the creative arts school counselor, the counseling relationship incorporates both creative art materials and the creative process as part of the therapy process. This differs from a traditional counseling approach that largely focuses on the client's verbalizations as the primary aspect of the therapeutic relationship.

While these guidelines and differences pertain to student members of the APT and AATA, students enrolled in other graduate programs (e.g., counseling psychology programs) do not necessarily receive training in creative arts counseling. A study of elementary school counselors and their use of play therapy in the schools, for instance, found that 67% of participants had not taken a university-

level play therapy course, 21% had taken one university-level play therapy course, and only 12% had taken two or more courses (Ray et al., 2005). Participants indicated that their lack of training was a key barrier to providing play therapy in the elementary schools where they worked. The researchers concluded that less training resulted in less play therapy for school-based clients.

Creative Arts Counseling Techniques: Definition, Process, Age Appropriateness, and Use With Diverse Populations

This section focuses on actual techniques the creative arts school counselor uses with children and adolescents in schools. Discussion of each technique addresses three areas: (a) definition and description of the processes and strategies associated with the technique; (b) the appropriate age for the technique; and (c) use of the technique with culturally diverse youth. The creative arts counseling techniques discussed in this framework are play therapy, art therapy, drama therapy, poetry therapy, and sandplay therapy. The purpose of this section is to familiarize practitioners and interested students with the various ways in which creative arts counseling is practiced in schools and among developmentally and culturally diverse youth.

Play Therapy

Play therapy definition and process. Axline (1947) described play therapy as "an opportunity which is given to the child to 'play out' his feelings and problems just as, in certain types of adult therapy, an individual 'talks out' his difficulties" (p. 9). Schaefer (1993) defined play therapy as "an interpersonal process wherein a trained therapist systematically applies the curative powers of play to help clients resolve their psychological difficulties" (p. 3). What happens in play therapy depends largely upon the approach taken in the session. Different theoretical approaches to play therapy incorporate different techniques and strategies. The commonality across approaches is that the creative arts school counselor always uses play to develop rapport and communicate with the child. Three prominent types of play therapy are (a) behavioral play therapy, (b) child-centered play therapy, and (c) structured play therapy (Cochran, 1996).

In behavioral play therapy, the creative arts school counselor uses play to help the child relax and role play alternative, more adaptive behaviors (Cochran, 1996). Play therapy largely relies on helping the child be an active participant in behavioral change and management. The bridge technique is an example of one strategy. The creative arts school counselor encourages the client to draw a bridge that extends from current behavior to the way he or she would like to be. The client then spells out the sequential steps that must be taken to achieve this new vision of self.

Child-centered play therapy focuses on the use of play to help children self-actualize through self-expression (Cochran, 1996). The child-centered philosophy of play therapy believes that play is the natural, developmentally appropriate way that children communicate, that children will naturally grow and mature, and that children can act responsibly and move in positive life directions (Landreth, 2002). Having children draw a picture that illustrates how they view themselves is an example of a child-centered technique.

Like the child-centered approach, the goal of structured play therapy is the child's self-expression and self-actualization. The difference between the two, however, is that the structured play therapist identifies barriers that interfere with the child's healthy development. Upon identifying the problem, the creative arts school counselor directs the child to develop skills aimed to overcome it. One example is the creative arts school counselor who discovers using play that the child experiences significant peer conflicts at school. The counselor then shares this observation with the child and engages in directed play therapy experiences aimed to enhance peer relationships.

Play therapy age appropriateness. Play therapy is appropriate for preschools and elementary schools with young children aged 10 and under who lack abstract verbal reasoning skills. The language of children is that of play; hence, understanding and communication is enhanced through play rather than verbal communication. This is in direct contrast with traditional talk therapies (Clauss, 1998).

Play therapy with culturally diverse youth. Play therapy is an effective tool in work with culturally diverse students in school settings (Cochran, 1996; Kalish-Weiss, 1989; Shen & Herr, 2003). Because the language of play therapy is play, cultural differences such as language that may otherwise interfere with the counseling process are not an issue. Many diverse cultures are context-dependent, meaning they rely more on context and nonverbal communication than the spoken word. Traditional counseling, however, is often focused on the client's direct verbalizations. Play therapy is culturally syntonic in that it naturally promotes the creative arts school counselor's focus on context, meaning how and with what the child plays. Additionally, a common practice

is for play therapists to name the emotions the child indicates through play. For the student for whom English is a second language, the counselor's naming of feelings not only allows for greater insight and identification, but also expands the student's vocabulary for emotions (Cochran).

Cochran (1996) examined how play therapy helps culturally diverse students overcome educational barriers such as difficulty learning cognitive material, social problems, and assimilation stress. Children's diverse cultural values may interfere with their ability to perform in a classroom with different cultural norms (Clauss-Ehlers & Lopez Levi, 2002). For instance, if a child's culture is group oriented, he or she may have difficulty performing in a competitive, individualistic classroom setting where class participation and individual decision making are required. Play therapy enhances these academic skills as the creativity of play provides decision-making opportunities such as with what and with whom to play during a session.

Social problems can be another impediment to school success. Culturally diverse students may feel they do not fit in with their majority classmates and teachers. They may feel misunderstood or rejected, which can lead to poor attendance and missed academic material. Friend-making groups can be organized in diverse school settings where children develop a common interest, activity, and connection through play (Cochran, 1996).

Assimilation stress refers to the stress that individuals experience when they move from their culture of origin to a new host country. Stress occurs as individuals try to adapt to the new country's values, language, and work force; cope with their immigration experience; drop to a lower social class status that results in less economic mobility; and confront feelings of isolation and loneliness (Clauss-Ehlers, 2006). For the immigrant child in the U.S. school system, assimilation stress develops as he or she tries to master a new language, learn course content in the new language, adjust to the culture of the U.S. educational system, and establish peer relationships.

Due to a drop in social class standing, both of the child's parents may now have to work, leaving less time for parent–child contact and support. The immigrant child may also be mourning the loss of loved ones in the country of origin, particularly if the child's parents came to the United States first and he or she was being raised by grandparents who acted as surrogate parents. Given the loss of family in the country of origin, play therapy is culturally appropriate in that it has been shown to reduce separation anxiety (Milos & Reiss, 1982). Because play allows children to express themselves, they can play out feelings of separation, stress, loss, sadness, anger, fear, and anxiety.

Shen and Herr (2003) examined the status of play therapy in Taiwanese elementary schools to determine its compatibility with Chinese culture and possible expansion in Taiwan. These investigators wanted to determine how counselor educators and elementary school counselors perceived play therapy, how they perceived play therapy in school counseling, and how they perceived the adoption of Western play therapy in Taiwanese society. They found that play therapy in Taiwanese society had "developmental potential" but also faced a "disadvantaged environment."

With regard to developmental potential, Shen and Herr (2003) found that research participants were positive about the expansion of play therapy in Taiwan, agreeing with the benefits play can have for children. Focusing on how play helps children communicate, one participant said that play therapy is more beneficial for Chinese children than American children because "[American] kids are more verbally expressive than ours are" (p. 32). Certainly, this view corresponds with culturally diverse youth from less traditionally expressive cultures who have recently immigrated to the United States.

Disadvantaged environment refers to cultural and societal barriers associated with the expansion of school-based play therapy in Taiwan. One participant wrote, "[The problem] is that most parents … think that play is a waste of time . . .. Many elementary school teachers even think the same way" (Shen & Herr, p. 33). Because environmental foundations for play therapy support are not always present in Taiwan, public education and outreach are increasingly important. Interestingly, this finding is not so different from the clash between therapeutic and educational cultures discussed earlier. Clearly, greater professional training and public awareness about the benefits of play are needed to provide a more comprehensive approach to creative arts counseling in school systems at home and abroad.

Art Therapy

Art therapy definition and process. Shostak (1985) defined art therapy as a "psychotherapeutic intervention that focuses upon art media as primary expressive and communicative channels" (p. 19). Art therapy provides both visual and verbal ways in which children can express themselves. Children tend to be open to the art-making process as it is less threatening than engaging in verbal expression about difficult issues.

Like play therapy, what occurs in an art therapy session depends upon the art therapist's theoretical approach. Strategies can vary from having a child create a collage that illustrates how he views his family to having a child draw a series of objects that illustrate her home life. In the more structured approach, the art therapist either selects the media to be used in session or presents a limited choice of materials. In the less structured framework, the client

chooses from a range of materials. Like play therapy, theoretical orientations to art therapy include behavioral, child-centered, and structured art therapy.

Objectification is one process that occurs in art therapy. *Objectification* refers to the "process through which the [child or] adolescent externalizes threatening feelings and ideas onto a neutral art form" (Kahn, 1999, p. 293). Having projected these feelings outwardly, youth talk about them from a distance and slowly incorporate them into a sense of self. Objectification addresses resistance as the feelings reflected in the art objects remain an ongoing symbol of what the child experiences. While the child may subsequently deny these feelings or experiences, the art therapist can refer back to the artwork and inquire about its significance over the course of counseling.

Despite the benefits associated with art therapy, it is used less often in school settings. Kahn (1999) attributed less use to a lack of training, the misconception among counselors that they themselves must be artistically inclined, and the inability to match art directives with counseling goals. She recommended that the schools invested in art therapy start by setting up an art station. The next step is to normalize the use of art in counseling by sharing its purpose with students, parents, and colleagues. Trust can be further developed by talking about confidentiality during the initial session and explaining that artwork will not be shown to others without the student's permission.

Kahn (1999) provided a model of integrating art with counseling in school settings. The key is to recognize relevant objectives at each stage of counseling and choose art directives that reflect those goals (Kahn, 1999). As counseling directives change throughout the process, so must the art directives given to the client. The three stages in Kahn's model are (a) entry, (b) exploration, and (c) action-taking.

The *entry stage* refers to the initial phase of counseling where trust is a major goal. Because therapeutic rapport is critical at this juncture, Kahn (1999) recommended art productions that foster communication. Art directives are open ended and allow students to share who they are with the art therapist. Two examples are "Tell your story," and "Make a collage about who you are" (Riley, 1994).

Exploration is the second stage and reflects the part of the process where the client increasingly explores his or her problems. Art directives at this point are concerned with the actual problem areas presented by the client. Directives during the exploration stage tend to be more structured. Two examples are "Create a collage that depicts your understanding of why you are coming to counseling" and "Choose a picture that represents your involvement in your academic work" (Kahn, 1999).

During the *action-taking stage* the client examines solutions to problem areas. Here relevant art directives focus on setting action-oriented goals that promote change. Specific goals and potential barriers are also discussed. Kahn (1999) provided examples of art directives that reflect this stage of counseling that include "Draw one time when the change that you want to occur did happen, even if just a little" and "Draw yourself in a scene 15 years from now. What goals will you need to reach during this time?"

Art therapy age appropriateness. Art therapy is appropriate for use in preschools, elementary schools, middle schools, and high schools. Like play therapy, art therapy with young children provides a nonverbal means of self-expression. For older children, adolescent developmental needs of separation and individuation are met in that adolescent clients have control over the process, are provided with a creative outlet, and have the opportunity to use media that illustrate group symbols (Riley, 1994). The ability to externalize feelings onto artwork can help adolescents be less defensive during initial phases of counseling. Less defensiveness sets the tone for an atmosphere where the adolescent client feels accepted by the adult counselor. This can be a unique experience for adolescents who struggle with authority and feel adults in general do not support their experience.

Art therapy with culturally diverse youth. Little research and writing exists about conducting art therapy with culturally diverse youth. Campanelli (1991) stated that art therapists who work with diverse populations must be trained in how "symbols and images in art may have different meanings depending on the client's ethno-cultural background: preferences regarding the use of line, color, and form may vary because every culture has a unique approach to art" (p. 34). It is the art therapist's responsibility to be aware of these different forms of art expression so that artwork in counseling is not misread. For instance, a Mexican American student may draw figures with heavy outlines, because this type of drawing is part of Mexican tradition and has nothing to do with wanting stronger boundaries in interpersonal relationships (Campanelli).

Kalish-Weiss (1989) described work with the Los Angeles Unified School District and the Los Angeles County Department of Mental Health to address some of the problems faced by culturally diverse families. The focus of the treatment plan was to offer play and art therapies for students. The treatment team included experts in art therapy who reviewed the various cases and determined what type of art and play therapy would most benefit the student. The success of the program included fewer symptoms among students (i.e., depression, attention problems, and academic difficulties), continued referrals from parents and the school system, and providing children with a way to discuss their problems (Kalish-Weiss).

Omizo and Omizo (1989) found that the Hawaiian children in their study had low self-esteem primarily due to growing up in a different culture and attending a Westernized school system. They developed an art therapy program to address the experience of Hawaiian students in Western-oriented schools who suffered from low self-esteem. Art therapy was provided through art activities conducted in small groups that fostered self-expression. The result of the program was that native Hawaiian youth experienced significantly greater self-esteem in social and academic arenas.

Drama Therapy

Drama therapy definition and process. The word *drama* comes from the Greek word *drao*, which means to struggle. The word *theatre* comes from the Greek word *theatron*, which means to show (Casson, n.d.). Drama therapy uses drama as the therapeutic method (Casson). The client shows the counselor her struggles through dramatization. The drama therapist works to provide a safe environment and engages clients with activities that include music, images, drawing, and movement. Participants take on characters and roles to act out conflicts through the drama presented. Drama therapy is a group technique that aims to increase self-awareness and expression.

Two approaches to drama therapy are psychoeducational drama and psychodrama. Psychoeducational drama utilizes dramatic productions to further self-awareness. Characters act out real-life problems over a brief period of time (one to five minutes). The goal of the staged dramatic presentation is to create a "believable and familiar situation of psychological and/or social significance with which the audience can identify" (Urtz & Kahn, 1982, p. 327). The three units of structure in psychoeducational drama are (a) exposition of the scene, (b) complication or development of the characters and scene, and (c) the scene where the drama is heightened.

Unique to psychoeducational drama is that the dramas end with the problem unresolved. The purpose of an unresolved ending is to encourage discussion among audience members who are now identified with the drama. This group discussion is facilitated by trained group leaders. Urtz and Kahn (1982) wrote,

> [T]he psychoeducational drama leaders evoke an emotional experience in their audience and explore the psychological, social, and educational issues involved by discussing the reactions of the viewers and helping the audience to relate the dramatized experience to their own lives. (p. 327)

Psychodrama is similar to psychoeducational drama in that it occurs in a group modality and characters must confront authentic issues. Psychodrama is not as brief as the psychoeducational approach, however, and does not necessarily end with issues unresolved. The structure of psychodrama also differs and includes the three phases of warm-up, enactment, and sharing (Casson, n.d).

In the first phase, warm-up, creative activities help participants be spontaneous and get ready to share. A group member is selected to express his or her experience through dramatic reenactment. In phase two, enactment, the group acts out scenes that represent the selected group member's life. A therapist facilitates this phase and works to foster catharsis, insight, and change. Sharing is the final phase of the psychodrama. Here group members explore the similarity and difference of experience between their lives and that of the protagonist. The goal of such sharing is greater awareness, the realization that one is not alone, and enhanced confidence and empowerment.

Drama therapy age appropriateness. Like art therapy, the use of drama therapy cuts across age groups and can be used in preschools, elementary schools, middle schools, and high schools. As with the other creative art therapies, drama therapy with young children provides a nonverbal means of self-expression. Young children may act out a character, for instance, through movement and interaction with other characters in a dramatic reenactment.

For elementary and middle school children, the drama therapy process can involve the telling of stories to one another about real-life situations. Storytelling is age appropriate and fits with the reading of stories that occurs at home and in the classroom. Theatrical experiences such as the use of make-up and costumes may further allow this age group to identify with the characters and stories they aim to portray. Even the creation of scenery can foster creativity, a sense of excitement about the process, and build confidence and resulting social skills in the process.

Drama therapy's peer-oriented nature makes it a developmentally appropriate intervention for adolescents. Dramatic enactment and the ensuing discussion with the audience directly correspond with the peer interaction that is so valued during this time. Adolescence is also a time of identity development and independence. Both are fostered through drama therapy in that adolescents get to bring their particular viewpoints to the characters that they embody. In addition, feedback, while facilitated by a group leader, is very much focused on input from peers. Given that some adolescents may rebel or feel distrusting toward adults at this point in their lives, the combination of facilitator and peer commentary is developmentally sound.

Drama therapy with culturally diverse youth. Almost no literature exists that explores the use of drama therapy with culturally diverse youth. Therapeutic Noh Theater is one approach that reflects an ancient Japanese dramatic art form (Green & Reinhard, 1995). Dating back to 14th-century sacred temple rituals, Noh therapy uses mime, music, and dance to convey a story. Protagonists use character masks to confront themselves in front of a mirror and engage in *kihon-no-kata*, a meditative approach to dealing with problems. The use of Noh therapy may be particularly appropriate with Japanese youth who have recently immigrated to the United States or who are familiar with the Noh tradition.

Drama therapy is also effective in helping culturally diverse youth work through complex sociocultural issues such as racism, discrimination, and grief related to the immigration process. Youth of all ages may have difficulty discussing such experiences and drama therapy can help them identify complex emotions. In addition, the creative arts school counselor may have limited personal experience with racism and immigration. Drama therapy helps the creative arts school counselor who is unfamiliar with these issues in that the sharing of their complexity stems from the youth's dramatic enactment. Thus, the culturally skilled creative arts school counselor who uses drama therapy must listen, empathize, and follow up on the cues communicated by clients.

Drama therapy is linguistically relevant for youth where English is a second language. Youth may have difficulty communicating in English. They may also be unable to access the emotions tied to a situation unless communication occurs in their language of origin (Clauss, 1998). Drama therapy provides a wonderful solution to this problem as youth can act out characters in their native tongue. The audience can consist of youth who speak the same language and thus provide further support and empowerment around the issue. For the facilitator who does not speak the same language, one strategy is to have the protagonist translate the main themes expressed during the drama. In this way, the facilitator understands what has been said and the youth is able to access the emotionality of experience through the language of origin (Clauss).

Poetry Therapy

Poetry therapy definition and process. Poetry is often considered a classroom tool and overlooked as a creative arts counseling technique. *Poetry therapy* refers to

> the use of poetry in a therapeutic experience that may involve a one-to-one relationship, a group process, or both. Such poetry is an ancillary tool that can be employed by any school of psychotherapy. The emphasis in poetry therapy is upon the person, while the accent in a typical poetry workshop is on the poem. The basic thrust of poetry in therapy is the use of metaphor and simile. (Lerner & Bettinger, 1991, p. 213)

Poetry therapy involves the reading and writing of poetry. It provides a healing experience in that individuals can share much of who they are through identification with a poem they have read or written themselves. The reading and writing of poems in creative arts counseling functions as a projective instrument through which emotions are expressed. Poetry therapy promotes greater self-expression, understanding of feelings, and self-esteem in a safe environment.

Gustavson (1999) presented several techniques that apply to the use of poetry therapy in school counseling situations. The *conversation poem* is a poem that tells a story through conversation. In using this technique, the creative arts school counselor provides an example of a conversation poem to the client who is then asked to write his or her own version. The creative arts school counselor can have the client write about a particular theme or the client can select a topic of choice.

I used to be . . . but now I am is another technique used in poetry therapy. Here clients are asked to write a poem about who they used to be and how they have changed to become their current selves. The *I used to be…but now I am* technique fosters insight about change over the course of time. Reflection about important life changes also provides the impetus for thinking about changes in the future and how counseling can facilitate the transformation process.

The *prose poem* is another technique. Creative arts school counselors introduce the prose poem format to their clients. Like the conversation poem, clients are asked to write about a particular theme or select their own topics. *Advice-giving poems* are poems selected by the creative arts school counselor that present advice about a given situation. Clients share their reaction to the advice given by the poet and subsequently write their own advice-giving poem.

In the *who I am* technique, the creative arts school counselor selects a poem that reflects a theme that is presented by the client in counseling. Gustavson (1999) used the example of the poem "I'm the Single Most Wonderful Person I Know" (Prelutsky, 1987) for clients who have conflicts with their peers. The main character brags about his personal qualities and then wonders why no one likes him. The poem concludes as follows: "[T]here's only one thing that I can't understand—why nobody likes me . . . not ever!" (p. 137). Upon reading the poem, the client is

asked to discuss the difference between self-esteem and arrogance (Gustavson). The client then writes his own *who I am* poem that incorporates both personal strengths and weaknesses.

With the *suggest the line* technique, the creative arts school counselor reads a poem out loud that reflects critical themes in the client's life. The creative arts school counselor then presents an alternative line to the poem that the client is encouraged to finish. Gustavson (1999) used President Jimmy Carter's (1995) poem entitled "With Words We Learn to Hate" as an example of this technique. The creative arts school counselor reads the poem and discusses themes of hatred and intolerance with the client. The counselor then presents another line (e.g., "with words we learn to celebrate"; Gustavson, 1999) that the client must subsequently finish.

Poetry therapy age appropriateness. Poetry therapy can be used with children from preschool through high school depending on the specific technique employed. For prereaders and writers, the creative arts school counselor can read the poem and encourage young children to share their reactions. Older children and adolescents who read and write can engage in all the aforementioned poetry therapy techniques.

Poetry therapy with culturally diverse youth. Poetry therapy provides an excellent way to capture the experience of culturally diverse youth. Critical to a culturally diverse approach is that diverse authors and themes are selected throughout the process. A culturally diverse application of the *conversation poem* technique, for instance, is Ntosake Shange's (1987) poem "Ancestral Messengers" (Gustavson, 1999). This poem depicts an authority figure who tells Señora Rodriguez why she cannot take her goat up to the 13th floor of a project building. The poem's theme centers on the clash between rural and urban cultures. After the poem is presented, the creative arts school counselor can have clients/students write poems about cultural differences (Gustavson, 1999).

Similarly, the *prose poem* techniques *I used to be . . . but now I am*, and *who-I-am* can focus on how clients view themselves in terms of their racial, ethnic, and cultural backgrounds. These mechanisms help clients focus on issues of identity, difference, and change. With the *prose poem* technique, for instance, Gustavson (1999) suggested the poem "Lil" (Gustavson, 1995)—a poem about an old woman who smells and is avoided by children and adults. After reading the poem, clients write a prose poem about someone who is misunderstood because they are of a different culture or race (Gustavson, 1999).

Sandplay Therapy

Sandplay therapy definition and process. Sandplay therapy uses sand as part of the healing process. Clients select and organize figures in a tray of sand that is usually 29" x 19" and 3" deep. The purpose of sandplay therapy is to

> 1) create in the sandtray a symbolic arena where conscious and unconscious dynamics can be presented and contained, and 2) allow for the rearranging and/or transforming of the objects in this symbolic arena in ways that foster and promote therapeutically positive changes in an individual's life. (Tennessen & Strand, 1998, p. 109)

Sandplay therapy incorporates Jungian theory as the use of sand is thought to encourage the unconscious mind to move toward its innate drive for healing (Weinrib, 1983).

Two approaches to sandplay therapy are the traditional approach and the directed approach. In traditional sandplay therapy, the sandtray is full of toys. The client works with miniatures (objects in the sandtray) as he or she chooses with no interference from the creative arts school counselor. The client is subsequently asked about what he or she created but no directives are given. Before the sandtray is disassembled, the creative arts school counselor photographs the client's work. Photographs are shown later when an interpretation is provided.

Directed sandplay therapy provides clients with guidance and direction. The directive approach believes that more involvement from the creative arts school counselor leads to greater change. Specific techniques are used to promote change more quickly. Directives include questions that ask clients to think about whether they want to change anything in the sandtray, requests to make specific changes, asking clients to depict particular scenarios, and questions about how miniatures are used in the sandtray (e.g., what a miniature wants to say and whether new miniatures should be introduced; Tennessen & Strand, 1998). Such directives are in direct contrast to the traditional approach that believes change will occur with nonverbal types of free play (Tennessen & Strand, 1998).

Sandplay therapy age appropriateness. Similar to art and drama therapy, sandplay therapy can be used in preschools, elementary schools, middle schools, and high schools. The traditional sandplay therapy approach is more relevant for younger, preverbal children as it allows the young child to move toward healing at a slower, less intrusive pace. Middle school and high school children are better candidates for directed sandplay therapy as they have the ability to use language. Youth in the formal operations

stage of development can grasp the meaning of directives, understand their symbolism, and work with miniatures in new ways.

Sandplay therapy with culturally diverse youth. Cultures throughout time have viewed sand and circles of Earth as having magical, healing powers (Tennessen & Strand, 1998). Sand paintings, for instance, were often used in traditional Navajo healing ceremonies. Sandplay therapy is culturally appropriate for cultural groups that are less comfortable expressing their emotions. For instance, Asian groups that may talk about educational problems rather than emotional distress and Latino groups that may somaticize may be more likely to be receptive to this less intrusive approach (Javier & Camacho-Gingerich, 2004).

Sandplay therapy is also culturally appropriate for non-Western groups that are context dependent and thus view the individual in context. Sandplay therapy, for instance, encourages the expression of the individual in context, allows for verbal and nonverbal communication, and provides a whole-body activity that fosters greater emotional expression than the mere focus on abstract words (Enns & Kasai, 2003). This is in contrast to Western psychotherapies that tend to focus on the individual in isolation, verbal communication, direct expression of emotion, a cause-and-effect model of problems, and the separation of physical and mental states (Sue & Sue, 1999).

Enns and Kasai (2003) discussed how sandplay therapy integrates Eastern and Western values and thus is culturally appropriate for Asian/Asian American youth. They presented four commonalities between sandplay therapy's Jungian roots and Asian traditions that include

> (a) a belief in a fundamental internal drive for wholeness and healing, and a human capacity to transcend current circumstances; (b) an appreciation of symbols, metaphors, and mythology as important forms of communication; (c) an emphasis on mind-body and person-environment connections; and (d) the importance of balancing apparently opposing psychic forces such as rationality and irrationality. (Enns & Kasai, p. 96)

Hakoniwa is a Japanese version of sandplay therapy that incorporates these dual traditions and is used with children and adults in Japan. *Hakoniwa* means miniature garden and the organization of the sandtray is considered a garden that reflects the client's experience. This orientation builds upon the concept of the Japanese garden that depicts artistic and spiritual values, also known as the *karesansui* or Zen dry landscape (Enns & Kasai, 2003). Hakoniwa and sandplay therapy are appropriate for those cultural groups that express feelings through nonverbal symbols, have a time orientation focused on the here-and-now and unity between mind and body, and use discipline and relaxation techniques to regain a sense of tranquility (Enns & Kasai).

Future Directions: A New Theory of Creative Arts Counseling in Schools

The national movement toward school-based mental health provides a timely opportunity to reconceptualize the role of creative arts counseling in schools. Empirical evidence underscores the positive benefits of creative arts counseling in schools. School-based creative arts counseling increases self-efficacy, self-esteem, insight, and sense of empowerment among students. Creative arts therapy programs have been empirically proven to decrease clinical symptoms such as depression and anxiety and enhance academic performance.

The foundational techniques of creative arts therapy such as play therapy, art therapy, drama therapy, poetry therapy, and sandplay therapy are developmentally appropriate for children from preschool to high school. Creative arts counseling is naturally conducive to a school environment in that it occurs where children live and does not necessitate that they travel to an outside office. Stigma is decreased by the very nature of creative therapies; teachers can be informed of therapeutic progress when given the appropriate parental consent, and the school benefits from greater harmony among its youngest participants.

The current author has introduced the term *creative arts school counselor* to further delineate the role of the creative arts counselor who works in the schools. It is hoped that the naming of such a term decreases the confusion between the creative counselor's role and that of the art or drama teacher, among others. Creative arts school counselors can be viewed as having a specialized area that combines the creative arts with counseling in the context of school life.

Despite what creative arts school counselors provide, multiple barriers exist in the provision of comprehensive creative arts counseling in schools that include (a) differences between the culture of creative arts counseling and the culture of school-based education; (b) difficulties creating a collaborative schoolwide team effort; (c) lack of support for clinical space and process; (d) problems with allocation of classroom time for creative arts counseling sessions; (e) interruptions by the academic school calendar; (f) need for cultural competence; (g) developing/improving credentialing for creative arts school counselors; (h) development of APA guidelines regarding the practice of creative arts counseling; (i) developing/improving curriculum

course offerings, programs, and requirements for creative arts school counselors; (j) additional courses in creative arts counseling in graduate-level counseling psychology programs; (k) additional training in research methods to provide a more comprehensive research approach for children's mental health; (l) eliminating the view that mental health services are not relevant to the school community; (m) helping the creative arts school counselor develop a clear role; (n) enhanced monetary support for creative arts counseling programs; and (o) educating the general public about the benefits of creative arts counseling.

A comprehensive approach to creative arts counseling in schools must largely focus on knowledge and communication. Given research that supports the efficacy of creative arts counseling in schools along with findings that indicate these techniques are underused, it is imperative that school administrators gain additional knowledge about creative arts counseling as an effective intervention. In addition, counselors themselves need additional training with regard to the theory and practice of creative arts counseling. This reality is particularly evident in research that indicates school counselors recognize the benefit of creative arts counseling but cite their lack of training as a key barrier to greater implementation (Ray et al., 2005).

Creative arts counseling research can take a more comprehensive approach by exploring broader trends that suggest what is effective with youth in schools. Truax and Mitchell (1971), for instance, examined process and outcome variables across several studies and found that empathy, nonpossessive warmth, and a genuine response to children and families in distress promote helpful outcomes. Additional studies and measurement techniques are needed that move beyond process and outcome research and narrative case studies. Future research needs to better isolate those factors that promote a positive counseling experience for children in educational settings. In this way, creative arts counseling research will have greater validity, reliability, and generalizabilty.

With regard to training and standards, a lack of training among counselors is a major barrier in and of itself. In the Ray et al. (2005) study, counselors identified lack of training as the second highest barrier to using play therapy. To further promote the effectiveness of creative arts counseling in schools, research needs to investigate types of creative arts counseling training available in school counselor programs and identify areas where training is not available (Ray et al.). From this research, graduate-level programs can begin to consider the ways in which they want to expand their course offerings so that creative arts counseling is part of the future school counselor's clinical repertoire. School districts that use creative arts counseling can also work to decrease barriers that interfere with the implementation of creative arts counseling by offering training and training materials to their school counselors.

The move toward a comprehensive approach to creative arts counseling in the schools requires that these barriers are addressed by all who are involved with creative arts counseling. A comprehensive effort means that educators, administrators, parents, graduate program administrators and educators, public policy makers, creative arts school counselors, and community advocates create partnerships that make the delivery of creative arts therapies available in schools. These efforts will provide alternative ways to meet the academic and emotional needs of schoolchildren who are developmentally and culturally diverse.

XXXIV
COUNSELING THE GIFTED AND TALENTED

CORISSA C. LOTTA AND ERICA A. KRUGER
University of Wisconsin-Madison
BARBARA A. KERR
University of Kansas

Introduction

Gifted and talented students are some of the most rewarding and challenging students for the school counselor. It is surprising, then, that these students are so seldom discussed in counseling training programs, despite evidence that these students are at risk for negative academic and social–emotional outcomes, including underachievement, dropout, stress, and depression (Colangelo & Davis, 1997; Kerr, 1991; Lovecky, 1993; Moon, Kelly, & Feldhusen, 1997; Silverman, 1993). While there is a great deal of literature and research on gifted students, very few school counselors have been required to demonstrate proficiency in these topics in the course of their education and training. Of course, this does not mean that they will not encounter these students in their school counseling work—gifted students are in every school at every grade level. It does, however, mean that school counselors may not have the knowledge required to identify and support this population, nor the ability to recognize the importance of providing services that address their specific needs (Adams-Byars, Whitsell, & Moon, 2004; VanTassel-Baska & Baska, 2004).

The Unique Academic and Social/ Emotional Needs of Gifted Students

The importance of being knowledgeable about these students is illustrated by the following vignettes. Although identifying information has been changed, each of these scenarios is based on actual individuals with whom the authors have worked in a counseling setting.

Matt, a third-grade Caucasian student at a small suburban elementary school, has a history of excellent school performance. He is well liked by all of his teachers, involved in extracurricular activities, and appears to have friends. A recent phone call from Matt's mother, however, indicates that Matt has been increasingly withdrawn and has been having difficulty sleeping.

Anita is a fifth-grade Latina student at a medium-sized urban elementary school who has been referred to the school counselor due to frequent absences and issues with homework completion. Teacher reports about Anita's performance are inconsistent. Most teachers report that Anita is struggling, but her math teacher notes that Anita's work is often excellent, although at times it is often incomplete or not turned in at all. Anita comes from a home in which Spanish is spoken as the primary language, and receives extra support, at school, because of her English language learner (ELL) status.

Jackie, a seventh-grade African American student at a large urban middle school, has been referred to the Student Services Team by her teacher because she has become increasingly disruptive in the classroom. In particular, her teacher is frustrated with Jackie's "attitude problem," including complaining about certain assignments, talking out of turn, and her tendency to negatively influence other students. Jackie's grades are average.

Before you read further, take a moment to consider the following questions: What are your initial impressions about these students and the issues that they are facing? What do you think your role as a school counselor would be in each of these situations? What interventions do you

think would be needed in order to best meet the academic and social/emotional needs of these individuals?

Now, think about how your responses to these questions might change if you also had the following additional information.

Matt was identified as gifted in first grade and has been excelling in the school's gifted programs. His teachers have described him as well behaved and creative, although he occasionally seems to be preoccupied and "in his own head." Matt's mother states that he has a vivid imagination and has always been highly sensitive. Although Matt has always had friends, he currently spends most of his time alone or with one particular friend, often playing elaborate fantasy games. Matt's parents went through a difficult divorce 2 years ago, and Matt now lives with his mother, seeing his father every other weekend. School has always been enjoyable for Matt, although lately he seems less enthusiastic.

Anita and her family moved from Mexico when Anita was in the first grade. Spanish is the primary language spoken at home. Because her parents both work several jobs to support them and their extended family, Anita is responsible for caring for her younger siblings and often does not get to her homework until late at night. Her math teacher states that Anita is a quick learner and often provides tutoring and support for other students in the class. When asked, Anita states that she loves school, especially math.

A review of Jackie's cumulative file indicates above average scores on standardized tests and strong academic performance throughout grade school. Previous teachers have described her as "well-liked, assertive, and determined." Jackie is very involved at the community center near her home and is widely considered a leader. She expresses a passion for acting and singing, and participates in her church choir and a local children's theater group. Jackie reports that she doesn't like school very much anymore because "it's boring."

Even though each of these stories is very different, there *is* a common thread that ties these students' experiences together—giftedness. These vignettes illustrate that gifted students are diverse, both in terms of demographics and in how their giftedness is expressed. In addition, these vignettes help us to understand why accurate identification and knowledge of the specific academic, social, and emotional concerns of gifted students are so essential. Without appropriate support, Matt could become depressed and begin to underachieve; Anita may never be identified as having high ability and receive the guidance she needs to reach her potential; and Jackie may become increasingly bored and frustrated and eventually drop out of school. It is easy to see how, if one is not familiar with the characteristics and issues common to gifted children and adolescents, the specific needs of these students may go unmet. Although the school counselor may recognize that there are problems or concerns, and even make efforts to intervene, without a comprehensive understanding of the role that giftedness plays in the student's experience, these intervention attempts may not be the most effective or efficient.

Mixed Messages

It is difficult to understand why school counselors are often not provided with the knowledge, training, and resources to effectively meet the needs of their gifted and talented students. In large part, however, it may be due to society's mixed messages regarding its hopes for the youth within our educational systems. On the one hand, there are proclamations that our nation must support our youth in reaching their potential in order to be innovative and competitive in a global economy. At the same time, however, society sends messages that suggest that nurturing the potential of those youth with outstanding talent is elitist (Colangelo & Davis, 2002; Galbraith & Delisle, 1996; Silverman, 1993; Winebrenner, 2001). The U.S. Department of Education's (USDE) report (1993) *National Excellence: The Case for Developing America's Talent* stated, "The belief espoused in school reform that children from all economic and cultural backgrounds must reach their full potential has not been extended to America's most talented students." This report went on to assert that within our schools, bright students are underchallenged and underachieving, and that the students who are most neglected are those who are economically disadvantaged or from racial/ethnic minority groups.

Given the complexity and confusion regarding how our society views and values the gifted, it is not surprising that education systems have been inconsistent in both the nurturing of these students and in the training of those who provide services to them. This inconsistency means that school counselors are often lacking information and training regarding gifted children, leaving them unprepared to recognize or meet the academic or social/emotional needs of these students (VanTassel-Baska & Baska, 1993).

Myths About Giftedness

Further complicating matters are a number of common misconceptions that hinder the provision of services for gifted children. You might encounter these in teachers, school staff, and individuals outside of the school. You might even struggle with them yourself. The following are

three myths that you may frequently encounter within the school setting regarding gifted children and their needs:

> Myth 1: Gifted kids are easily identified—"You'll know one when you see one."
>
> Myth 2: Gifted kids don't need academic or vocational guidance—"What do they need help with? They can *do* anything and *be* anything they want!"
>
> Myth 3: Gifted kids don't have any social or emotional problems—"They've got it all (and if they don't, they are smart enough to figure it out themselves)."

As we will examine in this chapter, these myths not only are inaccurate, but can also be dangerous to the academic and social/emotional well-being of gifted students. Unless school counselors are prepared to challenge these myths, there can be serious impact on the development of gifted students—gifted students will not be accurately identified, nor will they receive appropriate services. The academic repercussions of this include underidentification, boredom, frustration, underachievement, behavioral issues, and dropping out. Social/emotional repercussions include stress, anxiety, isolation, depression, and struggles with interpersonal relationships.

Providing appropriate services for gifted students requires a solid understanding of how giftedness shapes the way a child experiences his or her world. As described in the American School Counselor Association's (ASCA; 2005) position statement on gifted student programs, professional school counselors play a critical role in supporting their gifted students through counseling, consultation, and advocacy. School counselors need to be aware of and sensitive to the numerous challenges faced by gifted students—from an educational system that is often not designed to develop their academic potential to a social and emotional landscape fraught with internal and external challenges (Colangelo & Davis, 2002; Silverman, 1993). Without the understanding and support of a well-informed school counselor, these children may be left to navigate this difficult terrain alone, with little guidance into their futures. Furthermore, they may even be met with hostility or ambivalence—from peers, teachers, counselors, administrators—and an overall political climate that does not support intellectualism (Colangelo & Davis, 2002; Gallagher, 1991; Marland, 1972; Sherman, 1997; Silverman, 1993; Webb & Kleine, 1993).

Naturally, school counselors want to meet the needs of and support *all* students. As school counselors strive to be culturally competent, it is important to remember that sensitivity to diversity includes recognizing gifted students. Although there is not one specific comprehensive model of school counseling for gifted children within the literature, this chapter seeks to present information and research on some of the most salient issues and concerns faced by gifted students so that school counselors can be better prepared to understand and meet the needs of this population.

We recognize the challenges that limited budgets, lack of resources, and increasing student needs place on the school counselor. Erford (2003) noted that "over the past several decades, many professional school counselors and counselor educators have come to realize that the job descriptions and role responsibilities, coupled with the work and caseload realities, are overwhelming for all but the superhuman" (p. 12). Our hope is that by providing this information, it will help the school counselor to be more *effective* and *efficient* in recognizing and supporting gifted students. Furthermore, we hope that this chapter will not only inform the school counselor's own practice, but also increase his or her capacity to be an advocate and resource for parents and other school staff. Lastly, and most importantly, we hope to provide sufficient guidance to support school counselors in nurturing the potential of students like Matt, Anita, and Jackie.

Chapter Goals

Within this chapter, we will

- present useful models for understanding the academic and social/emotional issues of gifted students;
- present salient and culturally relevant research that will further a school counselor's understanding of the primary academic and social/emotional issues of gifted students;
- provide frameworks to help school counselors understand the multiple roles that they play in effectively serving the gifted population;
- illustrate how the literature is applied to practice and provide suggestions for interventions to aid in meeting the academic and social/emotional needs of gifted students; and
- explore recommendations for future research and practice with the gifted population.

Dispelling the Myths

Gifted children have many of the same needs as other children—they experience the same physical maturation process, they go through the same developmental stages (although often at an earlier age), and they may face similar family issues such as poverty, divorce, or alcoholism

(Webb & Klein, 1993). In addition, it has been well documented within the literature that gifted children also have academic and social/emotional needs specifically related to their giftedness, yet these needs frequently go unmet (Colangelo, 1991; Davis & Rimm, 1989; Kerr, 1991, 1994; Moon et al., 1997; Silverman, 1993). The myths presented in the introduction have a profound impact on how these students are perceived, and they contribute to a lack of understanding, support, and guidance for gifted students in the school setting. In the following section, we will take a closer look at these myths and the research that dispels them. In addition, we will familiarize the school counselor with important information about gifted issues and practices that he or she will encounter, including identification, curriculum guidance, career guidance, and social/emotional concerns.

Myth 1: Gifted kids are easily identified—"You'll know one when you see one."

There is a misperception that all gifted kids are alike—that they do well on achievement tests, have As in all subjects, are mature, well behaved, and enjoy school. In reality, however, there is tremendous diversity among gifted students, differences in what they look like and in how they think, feel, and act (Fiedler, 1993; Sanborn, 1979). Unfortunately, the methods of identification that are commonly used by school systems do not produce gifted and talented student populations that reflect this diversity. Historically, school-based identification and assessment practices have resulted in a disproportionate representation of certain types of students in gifted and talented programs, namely students who are White or Asian American, academically successful, English speaking, middle to upper class, and well behaved (Galbraith & Delisle, 1996; Hunsaker, 1995; Sherman, 1997). These are the kids who rise to the surface in the traditional classroom as "teacher pleasers" and are most likely to be recognized by teachers and school staff (Davis & Rimm, 1989). Because they match the assumptions of what gifted kids are like, they are typically the ones identified as gifted.

Students like Anita and Jackie who are also gifted but are not recognized by the traditional methods of identification are in those same classrooms. According to the U.S. Department of Education's (1993) report *National Excellence: A Case for Developing America's Talent* there are several groups of children who are often neglected in gifted programs. These are the gifted students who are non-White, are from a lower socioeconomic background, have a disability, are female (who are underserved in mathematics and science programs), are underachieving in school, are from rural communities, or are those whose talents are primarily in the arts (Colangelo & Davis, 2002; Davis & Rimm, 1989; Galbraith & Delisle, 1996; Silverman, 1993). They also include students who have behavioral problems, are LL, and come from families who are less familiar with how to successfully navigate through the school system.

The assumption that gifted kids are easy to identify reflects a misunderstanding of what it means to be gifted. Who, exactly, fits under the category of "gifted"?

Definition and identification of gifted. There have been numerous definitions of gifted and talented over the years. The federal definition of gifted and talented has changed several times since it was originally developed for the 1972 *Marland Report to Congress*. According to the National Association for Gifted Children (NAGC) Web site (2005), the current definition is

> The term gifted and talented student means children and youths who give evidence of higher performance capability in such areas as intellectual, creative, artistic, or leadership capacity, or in specific academic fields, and who require services or activities not ordinarily provided by the schools in order to develop such capabilities fully.

While the federal definition is comprehensive and inclusive, states and districts are not required to use the federal definition (NAGC, 2005). Furthermore, what is defined is not always what happens in practice. In practice, there is wide variability in the identification process, with some processes being more broadly defined (e.g., utilizing multiple criterion in multiple areas) and some being more narrowly defined (e.g., a single standardized assessment). One procedure for identification that is commonly used in schools is teacher referral (Naglieri & Ford, 2003). This method has received criticism because researchers have found that teachers often underrefer certain groups of students for gifted education screening and programs (Ford, 1998; Naglieri & Ford). Furthermore, the No Child Left Behind Act, the continued opposition to intelligence testing, and the severe underfunding of schools have created a situation in which most schools have had to cut back on the identification of gifted students or end the procedure entirely (Davidson, Davidson, & Vanderkam, 2004).

Many gifted students are overlooked because they are not academically successful across all subjects; that is, they are not straight-A students at the top of the class in all subject areas (Winebrenner, 2001). These same students may not do well on all portions of standardized assessments—such as an IQ test—therefore, their cumulative IQ may not meet certain cutoff criteria set by the school district. Many students are high ability in certain areas and below average in others (Galbraith & Delisle, 1996; Gardner, 1983). It is also possible that some children might be challenged by a

behavior or learning disability that "masks" their giftedness and impacts their performance in certain areas (Colangelo & Davis, 2002; Galbraith & Delisle, 1996; Silverman, 1993). Others may be bored by certain subjects; they may be excelling in one class where they feel sufficiently challenged, but failing another where they are uninterested or unmotivated (Galbraith & Delisle, 1996; Webb, 1994). Another group of gifted students who may have varied academic performance are those who are creative. These students tend to be less visible within traditional course work and less likely to be identified as gifted (Davis & Rimm, 1989; Renzulli & Reiss, 1986).

Additional factors, such as peer pressure, may also cause certain groups of gifted students to self-mask their own giftedness. This is especially true for adolescent girls. Although gifted girls in elementary school often surpass their male counterparts in academic performance, a significant shift can occur in the middle school years (Kerr & Nicpon, 2003). During adolescence, gifted girls begin to self-select out of higher level academic classes, particularly in the areas of math, science, and technology and may deliberately downplay their giftedness in order to conform to the expectations of their peer group (Callahan, Cunningham, & Plucker, 1994; Colangelo & Peterson, 1993; Frey, 1998; Kerr, 1994; Orenstein, 1994).

Current practices in identification are missing a large number of other students as well. There continues to be an underrepresentation of racial/ethnic minority and economically disadvantaged populations in gifted programming despite the fact that many researchers have called attention to this problem (Maker, 1996; Piirto, 1999; Silverman, 1993). Although evidence of intelligence is found in all children regardless of race, ethnicity, socioeconomic status, or geographic location, investigation into gifted programming has found that some minority groups are more likely to be served than others are (Colangelo, Assouline, & Gross, 2004; Schwartz, 1997). In her examination of national demographics of gifted programming, Ford (1996) reported the trend that Black, Hispanic, and Native American students have consistently been underrepresented in gifted education. The National Education Longitudinal Study of 1988 (NELS 88) found that about 8.8% of all 8th-grade public school students participated in gifted and talented programs (National Center for Education Statistics, 2000). Racial and ethnic groups were represented as follows: 17.6% of Asian students; 9.0% of White (non-Hispanic) students; 7.9% of African American students; 6.7% of Hispanic students; and 2.1% of American Indian students. The study also reported that states that use IQ-score cutoffs to identify gifted and talented students are more likely to have larger disparities among racial and ethnic groups. A growing body of literature has highlighted the fact that African American students are overrepresented in special education programs and underrepresented in gifted and talented programs (Ford, 1995; Ford, Harris, Tyson, & Trotman, 2002; Harmon, 2001; Morris, 2002; Patton, 1998). This literature suggests that the lack of identification of minority gifted students is due to a combination of factors, including cultural biases in assessment procedures, a lack of multicultural awareness on the part of referring teachers and school staff, and the existence of both covert and overt institutional racism. Negative stereotypes and inaccurate perceptions of the abilities of children from minority groups contribute to underrepresentation of racial/ethnic minority students (Ford, 1998; McCarty, Lynch, Wallace, & Benally, 1991; Patton, 1998).

As with adolescent females, the identification of gifted students of color may also be impacted by the influence that peer pressure has on these students' willingness to openly display their giftedness. Research suggests that this is especially true for academically successful African American students, who may receive negative feedback from both White and African American peers (Ford, 1994; Kitano, 1998; Kruger, 2004; Tatum, 1997). Concerns about social acceptance may further hinder accurate identification for this population.

According to the NELS 88 data, another group of significantly underserved gifted students were those who were economically disadvantaged (National Center for Education Statistics, 2000). Only 9% of students in gifted and talented education programs were in the bottom quartile of family income, while 47% of program participants were from the top quartile of family income.

Many believe that current definitions of giftedness do not adequately address culture, ethnic, economic, ability, and linguistic differences (Ford, 2001; Maker, 1996; McCarty et al., 1991; USDE, 1993). According to McKenzie (1986), identification procedures that use standardized achievement tests and intelligence scales reinforce social inequalities and miss some of the most promising students. Since the passing of the Jacob K. Javits Gifted and Talented Students Act of 1988, there has been a movement toward seeking alternative ways of identifying gifted children to better represent historically underidentified populations (Hertzog, 2003). Clearly, the identification and assessment of gifted and talented students is complex. A single test for all students is not an adequate approach to identify diverse students and talents (USDE, 1998). Many researchers and practitioners, as well as the NAGC (2005), recommend multiple assessment approaches to give students several opportunities to demonstrate their skills and performance potential (Maker; USDE). The ASCA (2005) advocates identifying gifted and talented students through the use of multiple criterion systems, which may include intellectual ability, academic performance, visual and performing arts ability, practical arts ability, creative thinking ability,

leadership potential, parent/teacher/peer nomination, and expert evaluation.

Using multiple intelligences can help to recognize students who would traditionally be left unidentified, particularly those from diverse cultures. Most well known is the work of Gardner (1983), who proposed the Multiple Intelligences Theory, which states that there exist not one intelligence but many, including linguistic, mathematical–logical, spatial–visual, musical, interpersonal, intrapersonal, and kinesthetic. The intelligences can function independently or be combined in any number of ways. Multiple Intelligences Theory has gained increasing interest, yet has not consistently found its way into schools (Galbraith & Delisle, 1996). Within most classrooms, the intelligences that are recognized and supported are those related to language and math. Students demonstrating the other intelligences are not as likely to have their gifts valued and nurtured. While Gardner's Multiple Intelligences Theory has not been empirically validated through research (Pfeiffer, 2003), it can serve as a useful way to identify more diverse students and guide counselors in supporting individual students' needs.

In addition to recommendations for multiple criterion and assessment approaches in identifying gifted students from organizations such as NAGC and ASCA, researchers also note the importance of considering the values and beliefs of the particular culture when choosing the procedures for identifying gifted and talented students (Maker, 1996; Tonemah, 1987; USDE, 1993). By utilizing both qualitative and quantitative data, the assessment of gifted students can be more comprehensive and inclusive.

Myth 2: Gifted kids don't need academic or vocational guidance—"What do they need help with? They can *do* anything and *be* anything they want!"

Those who are identified as gifted are often perceived as on the fast track to a lifetime of accomplishments and success, requiring little support or guidance (Galbraith & Delisle, 1996; Winebrenner, 2001). It is assumed that a gifted student will thrive throughout his or her school years and into any number of career areas. Little consideration is given to the multitude of barriers—academic, social, and emotional—that can interfere with the academic and vocational development of gifted children. It is surprising to many that students like Matt, who are identified as gifted and talented as early as elementary school, are at high risk for underachievement and dropping out of school. In addition, there is little understanding or sensitivity to the struggle the decision-making process can present to a gifted student who is multipotential, placing these students at further risk of not achieving their dreams and goals (Kerr, 1991).

Underachievement and dropping out. An area that has gained increasing attention among researchers is the underachievement of gifted students (Reis, Colbert, & Hebert, 2005; Seeley, 1993). According to Seeley, an underachiever is a student "who do[es] not achieve in the academic areas at a level consistent with his or her capability" (p. 263). According to the National Commission on Excellence in Education's (1983) report *A Nation at Risk,* over one half of gifted students do not achieve in school at the level predicted by their tested ability. Those who are gifted may also be at risk for dropping out of school (Renzulli & Park, 2000). There have been reports that up to 18% of all high school dropouts are gifted students (Solorzano, 1983). A study by Renzulli and Park further pointed out that many gifted dropouts are racial minorities from low socioeconomic backgrounds.

There are a variety of potential reasons that gifted students may perform below their potential, including disabilities (Mendaglio, 1993; Seeley, 1993), behavioral issues (Seeley), and boredom due to a curriculum that does not challenge them or meet their needs (Reis et al., 2005; USDE, 1993). As previously discussed, the pressures of peer acceptance can also have a direct impact on gifted students' attitudes toward academic achievement. As early as elementary school, some students (especially girls) report deliberate underachieving, or "dumbing down," so that they would be more accepted by peers (Colangelo et al., 2004; Colangelo & Peterson, 1993; Kerr, 1994). Another explanation for underachievement among the gifted is that schools are not appropriately serving this population. Seeley stated, "When schools do not actively identify giftedness among young children, culturally different children, gifted girls, or special populations, they 'underserve' these students who consequently underachieve in relation to their potential" (p. 264).

Pressures from nongifted peers not to perform well in school (Olszewski-Kubilius & Scott, 1992) may also contribute to dropout rates for gifted minority students. A number of researchers have reported concern about gifted racial/ethnic minority students who are underachieving because of their concern with being accused of "acting White" if they achieve academically (Ford, 1995; Kitano, 1998; Tatum, 1997; USDE, 1993). In a survey administered to 144 ethnically and economically diverse gifted students in grades 6 through 8, the most significant reason that respondents gave for lowered academic performance was their fear of losing friends (Reis, Callahan, & Goldsmith, 1996). Bell's (1989) ethnographic study of ethnically diverse preteens found that participants frequently avoided, or downplayed, success because they viewed their success as others' fail-

ure and were concerned that openly acknowledging their achievements would make others "feel bad" (p. 122). Bell has suggested that the conflict that this creates can become internalized as "ambivalence about success" and lead to a hesitancy to value one's own accomplishments, decreased academic risk taking, and underachievement (p. 123). Friendships with other achieving students have been found to be a protective factor against underachievement among economically disadvantaged, ethnically diverse high school students (Reis et al., 2005).

Some suggest that a prevalence of White teachers and lack of culturally relevant curriculum in gifted education programs can also make it challenging for gifted minority students to feel inspired to achieve to their potential, thereby leading to underachievement (Day-Vines, Patton, & Baytops, 2003; Tatum, 1997). Ford (2001) discussed the importance of students being able to "see themselves reflected (and affirmed) in the curriculum" (p. 142), through multicultural books, materials, lesson plans, discussions, and culturally diverse role models.

In a study of economically disadvantaged, ethnically diverse high school students, Reis and colleagues (2005) reported that negative interactions with teachers and "questionable counseling experiences" were also associated with underachievement (p. 116). In working with gifted underachievers, these authors proposed that school counselors focus on resilience for gifted students. This study found that protective factors for underachieving youth included involvement with supportive adults (including caring teachers and counselors), friendships with other gifted students, challenging course work, participation in multiple extracurricular activities, and the development of a strong belief in self. In addition, these students benefited from strategies for coping with negative aspects of their school, an urban environment, and for some, their families.

Poverty has a major impact on school success (Seeley, 1993). Seeley emphasized that the "underachievement and higher drop out rates for minority students is a function of *poverty*, not race or ethnicity" (p. 265). Living in poverty is strongly related to low educational achievement and low self-efficacy (Schunk, 1991; Yee et al., 1995), even for those who are considered gifted (Moon et al., 1997). Some reported that children from poor families are three times more likely to drop out of school than economically advantaged families (Horowitz & O'Brien, 1989), and others reported that they may be up to eight times more likely to drop out (National Center for Education Statistics, 1997). Poverty not only limits opportunities in education and careers, but also contributes to increased rates of substance abuse and depression (Yee et al., 1995). VanTassel-Baska, Patton, and Prillman (1989) conducted a national study of culturally diverse, low-income gifted students. These authors concluded that these students were especially at risk and would benefit from additional opportunities beyond those provided to more advantaged gifted students, such as tutoring, mentoring, and counseling. Kitano (2003) also advocated for qualitatively different services designed to meet the unique needs of economically disadvantaged students. Increasing involvement of parents and families, particularly of those at risk because of poverty, can also be a critical factor in improving academic success. For those gifted children who are immigrants, school counselors may need to help them and their families obtain special services to address linguistic and cultural differences, economic and health factors, and stress from culture shock (Harris, 1991).

An often overlooked group of gifted students are those from rural communities. There are unique barriers often faced by gifted students in rural communities, including small numbers of students, limited resources, and low socioeconomic status (Lewis, 2000; Milligan, 2004). These challenges contribute to gifted students' being underidentified and underserved in rural schools, leaving them at increased risk for underachievement (Benbow, Argo, & Glass, 1992; Luhman & Fundis, 1989). The school counselor must be sensitive to the ways in which geographic location can affect gifted students' access to resources. Key intervention strategies for this population of gifted students include helping them develop relationships with other academically engaged peers and assisting them in accessing enrichment opportunities, such as online classes and summer programs.

In a nationwide study, McCoach and Siegle (2003) found that gifted achievers and gifted underachievers differed in their attitudes toward school, attitudes toward teachers, motivation/self-regulation, and goal valuation. To provide interventions for these youth, these authors suggested that school counselors should assess whether underachieving gifted students value the goals of the school and whether they are motivated to reach these goals, stating, "If they value neither the task nor the outcome, they will not possess the motivation to give the task their best effort" (p. 144). Goal-setting and future-planning activities can help students find both intrinsic and extrinsic benefits to school.

Academic guidance. The academic needs of gifted children frequently go unmet, making academic guidance for gifted students a critical component of their education throughout their years in school (VanTassel-Baska, 1993a). School counselors are often in the position to provide consultation in helping parents understand the options and make decisions about education planning for their children. Over the years, there have been a number of strategies and recommendations for meeting the academic needs of gifted students, often creating controversy and confusion. Gifted education as a profession was so shaken by accusa-

tions in the 1980s of "tracking" and elitism from the federal level to the local level that gifted education offerings in many school systems underwent profound changes (Kerr, 1991). Programs that featured ability grouping were often watered down or eliminated; programs that emphasized acceleration were often replaced with enrichment programs that promised to be less elitist by focusing on more defensible characteristics than intellectual ability, such as task commitment. An even stronger push in the 1990s for "inclusion" (Salend, 2004) sent gifted children back to the regular classroom entirely, where teachers were expected to provide differentiated education for gifted children as well as children of various abilities and disabilities. The irony of the move away from grouping and acceleration is that virtually all the research on education of gifted students shows these two practices to not only be best for bright students, but also not harmful to nongifted students. Two groundbreaking meta-analyses of research on educational approaches for gifted students found clear evidence that ability grouping for gifted students was associated with higher academic achievement for gifted students and positive social and emotional outcomes (Kulik & Kulik, 1992; Rogers, 1998). In addition, grouping gifted students together has had little negative effect or no effects on nongifted students.

School counselors need to be aware of the various approaches, including benefits and drawbacks, in order to provide useful consultation to parents and to best facilitate a match between needs of the student and education options. The array of curricular alternatives for gifted students is far too broad to review thoroughly in this chapter. Three models have been chosen here for purposes of illustrating the major models in use in schools: acceleration, enrichment, and differentiation. School counselors who desire to investigate curricular options more fully should refer to some of the excellent books available on the topic, such as VanTassel-Baska and Reis' (2003) *Curriculum for Gifted and Talented Students*. In reviewing these three models, the counselor should keep in mind that most schools do not employ a single model or program to meet the needs of all gifted students. Unfortunately, many of these practices are fragmented and discontinuous in scope and unsatisfactory in meeting the full-time needs of gifted students. Counselors who wish to serve as academic advocates for gifted students need to understand that most gifted students in this country are *not* receiving an appropriate or challenging education, and that many of the problems that gifted children face are linked to the lack of services or programming that truly suit their needs.

Acceleration. Acceleration is an approach that involves "moving students through an educational program at rates faster, or at a younger ages, than typical" (Colangelo et al., 2004, p. xi). It has been demonstrated that acceleration is effective, is economical, and can benefit students from poor schools as well as those from wealthier schools. Further, it has been suggested that acceleration may be the only alternative for meeting the curricular needs of gifted students growing up in most rural settings where resources, both personnel and economic, are limited (Benbow et al., 1992; Milligan, 2004).

Early admission. Early admission is thought to be the easiest form of acceleration, but the policies and politics of school districts and state education agencies may make it difficult indeed (Colangelo et al., 2004; Kerr, 1991). In a school district where little else can be done for gifted students, such as in many rural settings, early admission to kindergarten is a sensible choice for any child who has good social skills and emotional development for his or her age (Kerr, 1991). The school counselor who wishes to be an advocate for gifted children should be knowledgeable about the literature that shows clear benefits of early admission for gifted children and be ready to defend those parents who are struggling with rigid policies that keep gifted children from receiving this easy and economical method of acceleration (Colangelo et al.).

Grade skipping. Grade skipping was once a common practice, but is now seldom heard of. Like early admission to kindergarten, critics assailed this practice because of their desire to keep all children of the same age together (Kerr, 1991). Nevertheless, skipping 1 or 2 years has been found to be an effective practice, particularly for the highly gifted and when the extent of acceleration matches the student's abilities (Swiatek & Lupkowski-Shoplik, 2003). Grade skipping can be an especially challenging situation when a gifted child has academic skills far beyond his or her age mates, but social and physical skills at or below that of his or her age mates (Roedell, 1990). This asynchronous development can be confusing for parents and teachers. It can also be confusing and frustrating for the elementary child. When they already have the academic curriculum mastered, do not fit in intellectually with their age mates, and are not supported in their intellectual interests by their teachers, these gifted students can become increasingly frustrated, losing their natural enthusiasm for learning. Further, some may cope with their frustration by developing behavioral problems, while others may begin to deny or hide their abilities in order to fit in with their classmates. Skipped students seem to experience few negative effects of being smaller or less mature than other students and tend to feel more comfortable and be more socially adjusted with their intellectual peers than their age peers

(Swiatek & Lupkowski-Shoplik, 2003). Also, any gaps in curriculum seem to fade in just a few weeks, as bright students rapidly catch up to their classmates' level. The earlier that grades are skipped, the better for bright students; that way they have most of their education at the proper level and are able to stay with their new friends longer (Colangelo et al., 2004). An excellent way to provide grade skipping is whole grade acceleration when a group or entire class of children is "skipped" together. With this method, gifted children not only receive appropriately challenging education, but also have a peer group of bright students with whom to relate.

Talent search. The talent search approach is another form of acceleration. The goal of this program, begun at Johns Hopkins University and now expanded to all regions of the United States, is to identify young students of extraordinary mathematical reasoning ability and to help them find appropriate curricular alternatives to develop their abilities (Colangelo et al., 2004; Kerr, 1991). In order to identify these highly able students, the concept of an annual talent search was initiated in 1972. The talent search model first used out-of-level testing to identify middle school students capable of college work. By the year 2000, talent searches had become one of the most rigorously studied forms of gifted education, and hundreds of thousands of students had participated in some aspect of the search. Although each of these talent searches keeps to the same basic program of using "out-of-level testing" as a means of identifying highly gifted students, precise identification criteria and educational options made available to identified students vary from location to location.

Most talent searches are open to students in the seventh or eighth grades who achieve high test scores on standardized achievement tests designed for their grade level (identification cutoffs range from the 95th to the 97th percentile on these tests). Students who meet these cutoffs and learn of the talent search through a counselor or school publications sign up independently to take one of the standardized aptitude tests offered on a national basis several times each year. Students request that these test scores be reported directly to a talent search institution. Students who achieve a test score that meets the criteria of that particular talent search are then invited to participate in several advanced educational opportunities.

Evolving from the talent search models are several promising practices that the school counselor can use (Stanley & Benbow, 1982). These practices include the Diagnostic Testing followed by Prescriptive Instruction (DT-PI) model. Using this model, high-ability students are given a standardized test, which is then analyzed to identify specific content areas of lower competence that require instruction. Students are then assigned to a teaching strategy that specifically addresses the area in which work is needed.

Advanced placement. Advanced placement (AP) courses, developed by the College Board, have been one of the most successful means of accelerating high school students into rigorous, college-level study (Colangelo et al., 2004). One million high school students a year participate in these programs in a wide array of courses. The 34 subject areas include physical and natural sciences, mathematics, literature, languages, music, art, and social sciences. Students who are successful on the AP tests given after the courses are completed may be able to skip college courses, allowing them to take more advanced courses in college and even finish college early. Participation in AP courses has been found to increase the chances that students will graduate from college and go on to advanced education. School counselors should encourage all bright students to take as many of these courses as will fit into their schedule, as well as encourage teachers to take the special training that will allow them to teach these courses. School counselors may have to advocate in order to get some students into AP classes if these students do not fit the stereotype of a gifted student held by teachers or administrators. Counselors may also need to provide extra support and encouragement to students who—due to the negative messages that they have previously received from peers and/or school staff—do not see themselves as capable of advanced placement work.

There are potential issues related to acceleration that school counselors need to be aware of and anticipate (Kerr, 1991). The acceleration model is likely to produce students in high school who have advanced far ahead of their peers in at least one area. These students may already have exhausted all the resources available to them in their area of talent in their high school. For instance, the student who has been radically accelerated in math may already have completed calculus after a few summers at summer institutes at university programs such as Johns Hopkins or Duke. This leaves the counselor with the job of determining (a) how to factor these courses into a student's graduation requirements and (b) how to provide this student with additional appropriate academic opportunities in either mathematics or related disciplines. Another related difficulty may be that the student who has experienced highly accelerated, intellectually stimulating classes during the summer may return during the regular school year only to feel bored and frustrated with the slow pace of high school classes. Counselors may need to help students deal with these frustrations by assisting them in discovering other sources of intellectual stimulation as well as in helping

them find ways of making the materials that they are studying more interesting to them.

One other outcome of accelerated programs is that students, for the first time, may have spent long periods with their intellectual peers (Colangelo et al., 2004). As a result, they have often made close friendships and have discovered a social group that has more importance for them than any they have previously experienced. Consequently, the return from a summer program or the return to a regular program from a highly accelerated program of any kind may be associated with feelings of loneliness and alienation. As with their academic transition, the school counselor can play an important role in helping gifted students successfully transition socially and emotionally back into their regular school environment.

The Enrichment Triad/Revolving Door Identification Model. Enrichment is another common method of curriculum modification and involves supplementing a student's regular curriculum with increased breadth and depth of material (Swiatek & Lupkowski-Shoplik, 2003). The Enrichment Triad/Revolving Door Identification Model (Renzulli, Reis, & Smith, 1981) is the system of identification and curriculum modification that is most widely used in schools in the United States today. The Enrichment Triad Model includes three types of student enrichment activities that progress in sequential, but qualitatively different, steps. These steps include Type I, *general exploratory activities*, in which students are exposed to a wide variety of content areas and topic experiences designed to help learners to understand their areas of personal interests; Type II, *group training activities*, which consist of materials, methods, and instructional techniques that enhance high-level thinking skills, facilitate feeling processes, may include creative problem-solving training, reflective thinking, training in inquiry, and other creative or productive thinking activities; and Type III *enrichment activities*, which provide students with opportunities to investigate a real problem by using appropriate inquiry methods, requiring students to have strong interests and task commitment. Type I and Type II are considered appropriate and valuable for all students, while Type III activities are thought to "require the special creativity, ability, and energy of truly gifted students" (Davis & Rimm, 1989, p. 162).

The Revolving Door Identification Model (RDIM) (Renzulli et al., 1981) is paired with the Enrichment Triad Model. The RDIM is the process by which a pool of approximately 15% to 20% of the student population is selected. Generally, these are students with above-average intelligence, as measured by a variety of intelligence instruments, who have also shown evidence of ability to commit themselves to tasks, and who have above-average creativity. These students are exposed to Type I activities and receive Type II process training usually on a weekly basis. During the time, the students are exposed to Type I enrichment activities and Type II training, and it is assumed that they will become interested in the more challenging Type III activities. Students "revolve into" these options as they show an interest and a desire to pursue advanced work.

Generally, an Enrichment Triad/RDIM gifted program is implemented through a pullout process. That is, students are pulled out of the regular classroom for a period of 1 to 3 hours a week in which they engage in special activities. Usually, these activities take place in a resource room with a resource teacher specially trained in facilitating student exploration in the three types of activities.

The advantages of the Enrichment Triad/RDIM are fourfold: (1) these programs do allow at least some interaction with intellectual peers, (2) only a small number of teachers are needed, (3) the teacher can concentrate on thinking and research skills because he or she does not have responsibility for basic skill development, and (4) the absence of the gifted child from the regular classroom allows other children to rise to the attention of the teacher.

According to Belcastro (1987), however, there are clear disadvantages for at least some gifted students, because pullout programs that are tied to the regular curriculum are quite rare. Instead, he said, many such programs are a smorgasbord of offerings that have no common thread and are disconnected from the regular curriculum. Too often, this becomes a collection of games and activities that do not actually constitute a qualitatively different curriculum for the gifted child. For example, the problem-solving strategies that are taught may not be associated with such content areas as biology or mathematics but instead with puzzles or mysteries. Creativity is used in future problem solving rather than applied to mathematics or social studies. In addition, the inclusion of so many non-gifted students with very gifted students often results in a dilution of the program so that it is not truly a differentiated program. In addition, a program that meets for only a few hours a week has a minimal impact on the academic experience of the gifted student (Belcastro). Time out for the gifted program is often time misused. Moreover, students who miss regular classes in order to go to the resource room are often made to finish the work they missed at other times, thus putting more pressure on them. Because of the short amount of time, students gain few opportunities to interact with their intellectual peers. Faster pacing is seldom used, although the model allows for it, and even though a wide variety of strategies is encouraged, in practice this often does not occur.

Perhaps Belcastro's (1987) criticism of the politics of pullout programs is most apt. He said that although the Enrichment Triad Model is simple and expedient, it creates the impression that something substantial is being done for the intellectually gifted. The pullout program, he said, both delays *and* impedes progress toward sounder programs because it allows administrators and teachers to be comfortable with the status quo. Regular teachers often resent the program because gifted students find the classes more exciting or stimulating than their own, and project planning is difficult due to the timing of programming. In practice, programs tended to be isolated, fragmented, time limited, and lacking in continuity with other school programs. Furthermore, negative attitudes toward gifted students in the regular classroom can be instilled when the pullout program causes an interruption of regular school programs.

The Renzulli Enrichment Triad/RDIM may lead to problems when highly gifted students are not admitted to the gifted education program. Because Renzulli's identification procedures involve selecting students of above-average intelligence who are task committed and who demonstrate creativity, it is often possible that a very high-IQ student will not be admitted. Most frequently, the very high-IQ student who is not admitted to an enrichment program is an underachiever whom teachers have a difficult time motivating. Occasionally, however, teachers or program directors have vented their resentment or hostility toward very bright students by denying them access to the program based on a subjective judgment that the student is "test-bright, but not creative" (Kerr, 1991). The unhappy scenario that often unfolds in this case is one in which the student and parent appeal their case to an administrator or board. The gifted student then is admitted to the gifted program only to learn that there is little there to meet his or her needs. Extremely bright students may feel that enrichment programs are too insubstantial and slow paced for their intellectual needs. Students in these situations may seek the counselor's aid in finding more challenging activities or even in making the enrichment program more rigorous.

Differentiation. As statewide, high-stakes testing has gained impetus throughout the United States, school administrators and teachers find themselves in the position of having to be constantly concerned about maintaining high overall scores for their school in order to receive an adequate "report card" from the state (Winebrenner, 2001). Most schools have chosen to raise their school scores by putting tremendous emphasis on raising the achievement of the lowest-scoring students. As a result, gifted students, who are already facing decreased programming as a result of budget cuts, are truly left behind.

However, grouping gifted students together in their own classroom for either acceleration or enrichment has been vigorously and persistently attacked by critics of gifted education who believe that any grouping is elitist and detrimental to disadvantaged or less academically able students (Colangelo et al., 2004; Richert, 2003). As Richert pointed out, identification practices that led to school segregation by class and ethnicity and unfair differences in the quality of the content and the instruction between gifted and regular classes have sometimes left gifted education vulnerable to these criticisms. Although efforts are being made to improve identification practices, the reality is that, with the increasing frequency of severe cuts to education budgets, gifted education classes are at continued risk for termination.

Therefore, it is likely that in the near future, most gifted students will spend most of their time in the regular classroom, with a regular classroom teacher, rather than in a resource room or self-contained classroom with a trained educator of gifted students. Of course, for most of the history of American education, this has been the way gifted students were educated. However, in the one-room schoolhouse, gifted students were allowed to work independently at their own pace and in larger schools, gifted students were skipped a grade or more or graduated early. In the present day, especially in more complexly organized schools, with less curriculum flexibility, it has been difficult for teachers of gifted students to implement even these simple options (VanTassel-Baska, 2003).

A number of scholars have developed creative responses to this situation. Richert (2003) developed innovative strategies for identifying giftedness that she claimed were ethical, equitable, and defensible in Project Apogee. In an attempt to overcome the tendency of gifted programs to serve mainly White, middle-class populations, Richert used local norms and a strategy for selecting the top 25% of every identifiable demographic group for differentiated education. The Maximizing Potential Model (Richert & Wilson, 1994) provided instruction to teachers in differentiating subject areas for individual interests, learning styles, and achievement levels. This model identified the strengths of all students through needs assessment, and then provided a wide variety of teaching strategies to maximize student strengths. Although in Project Apogee not all differentiation was within the heterogeneous classroom, the large numbers of children identified as having potential resulted in improved practices in regular classrooms. The use of Richert's identification procedures and Maximizing Potential model have led to substantial changes in numbers of students identified as well as improvements in school achievement on high-stakes state performance assessments in Connecticut, Louisiana, and New Jersey. Richert said, "Overall these results demonstrate that with

intensive staff development and on site follow up, these strategies maximize students' cognitive, affective, and ethical potential" (p. 155).

Finally, VanTassel-Baska (2003) has developed detailed guides for curriculum differentiation for gifted students in the regular classroom. The Integrated Curriculum Model (ICM) takes into account the paradigm shift in educational reform focusing on learning communities and maximum competency standards. In addition, she has adapted the national and state standards to the needs of gifted students by emphasizing higher level thought processes in differentiation techniques for the regular classroom. The curricula developed by VanTassel-Baska and her colleagues include the possibilities of acceleration, increased task complexity, increased depth, increased challenge, and application of creativity to the work of the gifted student. Assessment of students is realistically based on available sources of information. Interventions are keyed to learner outcomes in a carefully planned design. Materials are provided to teachers so that each teacher need not reinvent curriculum for gifted students. Finally, a strong focus on evaluation keyed to learner outcomes ensures accountability. Evaluations of the implementation of the language arts curriculum (VanTassel-Baska, Bass, Ries, Poland, & Avery, 1998), the science curriculum (VanTassel-Baska & Baska, 2004), and the use of the ICM as a whole (VanTassel-Baska, Zuo, Avery, & Little, 2002) have shown that teachers can effectively implement differentiation of the curriculum for gifted students and can attain desired learner outcomes. Curriculum differentiation for gifted students in the regular classroom can be enhanced by the assessment techniques, the intervention strategies, and the teacher training components of many existing models of gifted education.

Some of the same criticisms that are leveled at enrichment hold true for differentiation in the regular classroom. When gifted children receive only a small portion of a teacher's attention, their education becomes fragmented (Colangelo et al., 2004). Teachers may become overwhelmed by the need to individualize education for each student, and end up resenting the amount of time and energy required by gifted children who use up educational resources rapidly. It takes a great deal of training and professional development to meet the needs of gifted children in the regular classroom in a skillful manner. Because differentiation models are fairly new, few teachers have been exposed to them in the course of their education.

Problems that can occur with differentiation models include isolation, distraction, and the pressure to help other children (Kerr & Kurpius, 2005). When there are only one or two gifted children in a classroom, bright children have little opportunity to interact with gifted peers. The gifted child can feel lonely and odd, and begin to camouflage his or her giftedness as a coping strategy (Buescher, 1986). Feelings of isolation may be further exacerbated for the gifted child of color if he or she is placed in a predominantly White classroom or for any child for whom the cultural characteristics of his or her classmates are very different from his or her own (Grantham & Ford, 1998). It is important for the school counselor to be aware of, and watch for, signs of boredom and/or withdrawal within the classroom. Research suggests that girls are more likely to withdraw as demonstrated by an unwillingness to go to school, poor class participation, daydreaming, and sadness, whereas boys are more likely to act out behaviorally (Kerr, 1994).

Distraction is a problem observed when gifted children in a differentiated classroom are given workbooks or computer-based instruction as tasks while the other children are being taught a regular curriculum. Gifted children may rapidly work through the advanced problems they are given and then spend the rest of their time doodling or reading "fun" material. On the computer, the gifted students may stray from the online curriculum to engage in instant messaging and playing games without the teacher's noticing that they have become distracted.

Finally, one of the most difficult situations for gifted children is pressure to tutor and help other students. Although they may at first enjoy their status as a peer tutor, gifted children may become tired and frustrated and begin having conflicts with their peers as a way of escaping their burdensome role. School counselors may hear parents of gifted children in the regular classroom complain that differentiated education for the gifted amounts to their children being used as tutors for children who are learning less rapidly.

When providing academic guidance, school counselors may find themselves in the position of consultant—providing parents with information about various educational approaches and assisting them in advocating for the needs of their student. Counselors may also need to work closely with teachers in developing curriculum to facilitate the development of gifted programs that are developmentally appropriate, carefully differentiated, and proactive.

Career guidance. Even Terman's (1925) highly gifted subjects from his historical study were often found to have had great difficulty translating their extraordinary intellectual ability into meaningful, productive work. Over half of the gifted women became homemakers despite earlier career aspirations; and even those who eventually achieved satisfaction and success had difficulty deciding among many career options (Terman & Oden, 1935, 1947). More recent clinical case studies and research on the gifted show that the path from youthful talent to adult accomplishment is not always straight and smooth. National Merit Scholars (Watley, 1969), Presidential Scholars (Kaufmann, 1981), and

graduates of major learning programs (Kerr, 1985) all have been found to experience problems in career decision making or life planning.

One missing ingredient in the development of most gifted individuals is career guidance (Kerr, 1991). Although special education programs exist for about one third of the gifted in the nation's schools, few include a guidance career component. In a study surveying the parents, school personnel, and related professionals, Moon and colleagues (1997) found that there were strong perceptions of need for career guidance and planning of postsecondary education for gifted children and their families. Career guidance may be particularly powerful for gifted students from lower socioeconomic status or from rural settings. Students from disadvantaged backgrounds often do not have enough contact with those who could provide academic and vocational information and feel less informed about how to make career choices (Olszewski-Kubilius & Scott, 1992). These students may have limited knowledge of the world of work and a restricted sense of occupational options. Parents of these students, especially those who do not have personal experience with postsecondary education options, will also need resource information about how to support their gifted children in making appropriate academic and vocational choices.

While gifted girls and boys can both benefit from career interventions, girls seem to be at greater risk for not achieving their career goals (Kerr, 1994; Kerr & Fischer, 1997). Adolescence may be particularly difficult for gifted and talented girls, who often struggle with the conflict between achievement and affiliation needs (Clasen & Clasen, 1995; Kerr & Fischer; Moon et al., 1997) as well as with declining self-esteem (Greenberg Lake Analysis & American Association for University Women, 1991). It is also during this time that gifted girls' confidence and career aspirations begin to decline, initiating the gap between boys' and girls' career achievements that continues to widen throughout their lifetimes (Kerr, 1994).

One of the most important decisions that the school counselor will assist the gifted student in making is the choice of a college (Kerr, 1991). Gifted students are often unsure of their own characteristics and the ways in which their needs might be met by various kinds of higher education institutions. Bright students and their parents often have strong, and sometimes conflicting, opinions about college choices. Students, parents, and counselors are all often hampered by misconceptions of generalizations about what kind of college is best for gifted students. Some of the confusion about college choice is related to a lack of clarity about career choice.

There are several reasons why career interventions need to begin very early—as early as elementary school—for gifted and talented students and continue throughout schooling (Kerr, 1991). Many of the careers that gifted children find interesting require many years of advance planning. This does not mean that bright students should be pressured into making early career choices. Instead, career education and career guidance strategies should be infused into the curriculum to help gifted students progress through the stages of fantasy, exploration, crystallization, and commitment to a career.

Early emergence theory. This characteristic in the career development of some gifted students is usually not a concern for individual students, but is often the source of misunderstanding and concern for parents, counselors, and society. "Early emergers" (Marshall, 1981) are children who have an extremely focused career interest from a very early age. These children may become completely absorbed by their interests early in life and commit themselves to a career without exploring or considering other options (VanTassel-Baska, 1993a). This may be problematic for some, if this foreclosure creates a situation where a student feels locked into an early career decision and loses his or her love of learning. However, for others, this early vision of their career path means following their sincere passion and is more like a "calling."

Kerr's (1991) theory of career development for early emergence is based on the need to "scout" out specific, extraordinary talent, support early emerging interests, and provide adequate mentoring in the domain of talent. Neglecting early emergence means not noticing the talent or interest at all or failing to provide education and resources. Counselors and teachers need to be alert to the appearance of unusual talent and interests not only in traditional academic areas, but also in such areas as inventiveness and leadership. They should also be aware that a child's passion and brilliance at such recreational activities as video games, "Dungeons and Dragons," or skateboarding may be a sign of early emerging spatial–visual genius, verbal creativity, or athletic excellence, respectively. Ignoring these abilities because they emerge in play may be costly to the student's career development.

Despite the strength of the early emerger's passion, it is possible for it to be destroyed by others' belittling the talent or interest ("Who cares about someone who doodles and draws all the time instead of listening?"; "So what makes you think you will ever be able to get a job as an anthropologist?"; Kerr, 1991). It can also be done by insisting on "well-roundedness." Although the concept of the well-rounded person is deeply embedded in American educational tradition, research does not support the notion that eminent adults are knowledgeable in all fields or competent in all skills. Too often teachers and parents mistake a specialized interest as evidence of imbalance or poor adjustment when there is no basis for this evaluation. Sometimes parents or

schools actively disallow needed training (e.g., refusing to allow a mathematically precocious child to accelerate in math), causing a talent to wither. Finally, overly enthusiastic encouragement and pressure may also remove the intrinsic pleasure the child feels in the interest talent area. When a child's first, tentative explorations of piano playing show precocious ability, too intense a practice schedule and concentrated parental focus may kill the child's natural desire to play well.

Career guidance must begin early for early emergers so that their precocious interests do not fade away for lack of affirmation from adults (Kerr, 1991). Early emergers will need encouragement for their profound passions, and the counselor's role will most frequently center around protecting the student from well-meaning teachers who want to focus on making these children well rounded. Counselors can help early emergers find the mentors they need in their chosen domain and impress upon parents the importance of respecting the child's desires to pursue his or her unique interests even outside of school.

Career education and guidance for gifted students needs to take into account not only their special career development needs, but also their preferences for intellectually challenging materials and methods. Career materials are often boring to bright students, and well-written biographies of diverse eminent people may be much more appropriate than the generic career guidance booklets found in most career centers. Web sites for the various professions, and organizations specially geared to children with specialized interests can be valuable to bright children who want to get a taste of what it is like to be a physician, engineer, poet, entrepreneur, or politician. Finally, career education and guidance need to be based on the discovery of a vocation or purpose rather than on the search for a job. Teaching students how to "package" themselves via resumes and interviewing skills should be deemphasized in favor of teaching students the importance of career development as a search for *meaning*.

Multipotentiality. Multipotentiality is the cause of most gifted students' difficulties in career development (Kerr, 1981b). *Multipotentiality* is defined as the ability to select and develop any number of competencies at a high level (Frederickson & Rothney, 1972). Gifted students and those who are concerned with their guidance have long recognized that having multiple potentials can be a mixed blessing. Without appropriate career guidance, multipotentiality may become a curse.

Gifted students are often multipotential because they possess a high level of general ability, which makes them able to perform capably in almost any intellectual endeavor (Kerr, 1991). Unlike students of average ability, who must make academic and career choices based on their areas of greatest strengths, many gifted students must make their choices based on some other criterion than ability. Unfortunately, vocational interests, when measured at grade level by current standardized measures, are also of limited usefulness for career decision making. The evidence that multipotentiality poses a significant barrier to effective decision making is available from decades of research, primarily from case studies and longitudinal studies. Hollingworth (1926) found that the many subjects from the large pool of gifted students she interviewed had experienced considerable difficulty both in choosing from among their many interests and in confining themselves to a reasonable number of enterprises. From 1957 until 1984 at the Wisconsin Research and Guidance Laboratory for Superior Students (where the term *multipotentiality* was coined), researchers consistently found that the gifted students attending the laboratory had excellent grades across the board in their course work, high scores across achievement tests, and multiple expressed interests on vocational instruments (Frederickson & Rothney, 1972; Perrone, Karshner, & Male, 1979; Sanborn, 1979). In the Study for Mathematically Precocious Youth at Johns Hopkins University, Fox (1978) found that junior-high-age gifted students identified by the talent search were higher on most basic interest scales than nongifted students and tended to have patterns of interest that were not clearly differentiated. Finally, studies of high school juniors and seniors scoring in the 95th percentile on the ACT showed elevated interests across five of the six occupational theme groups, all except business operations (Kerr & Colangelo, 1988).

A multipotential student may take a vocational test only to learn that he or she is "similar" in interests and abilities to biologists, librarians, musicians, reporters, English teachers, and ministers. Attaining straight As and uniformly high achievement-test scores means that the student cannot make decisions based on what he or she "does best" (Kerr, 1991). After graduation from high school, the multipotential student may vacillate between career choices, delaying career decisions until financial need and the end of a nonfocused education drive the student to take a job by default. As an adult, the multipotential gifted individual may dabble in a series of jobs, finding success but little satisfaction in any. Parents, teachers, and counselors are puzzled throughout the disappointing and spotty career of the multipotential individual. They continue to insist, "But you could be anything you want to be!" not understanding that this is precisely the problem. Thus, for many gifted students, career decision making can be an existential dilemma (VanTassel-Baska, 1993a). Having many viable vocational options and choosing only one of your dreams means that there is the loss of another. There can also be the pressure to make the "right" choice and the fear of making the wrong choice.

Too often, multipotential students make misinformed or misguided career choices. Today's gifted students make career choices based on conformity with peers, money-making potential, and pragmatism, like the rest of their generation (Astin, Green, & Korn, 1988). Unfortunately, the decisions they make are often not related to interests, needs, strongly held values, or even finely developed talent. The study of college major and career choices of the upper 10th, 5th, and 1st percentile scorers on ACT composites (Kerr & Colangelo, 1988) and the study of the choices of those students who scored perfectly on at least one scale of the ACT (English, math, social studies, natural science; Colangelo & Kerr, 1990), showed that the majority of the gifted had narrowed their career interests to business, engineering, premed, prelaw, and communications. Recent surveys of college freshman have shown similar patterns, but with stronger interest of gifted students in computer technology and biomedicine (Astin et al.). Although perfect scorers had extraordinary abilities in English, math, science, and social studies, only a small fraction were interested in majors in those areas. It is difficult to achieve a perfect score on any of these scales without unusual amounts of extracurricular reading and home study. Yet, these young people, who may value the study of the liberal arts and sciences above all other activities, seem to be discouraged about actually pursuing careers in these areas.

When providing vocational guidance for gifted students, school counselors need to be aware of the struggles faced by gifted students in their decision-making process. Silverman (1993) stated,

> Career counseling for the gifted needs to be sensitive to their multiple interests, the existential dilemmas they face in making choices, their fear of making the error, their fear of being less than their ideal or not living up to their potential, the depth of their sadness over the road not taken, and their fear that if they try to nurture all of their potential, they will end up second-rate at everything. (p. 220)

Multipotential students from elementary school throughout high school will need assistance learning to focus on one task at a time; they will need help prioritizing among their many interests; and even more important, they must learn to understand how their developing sense of identity and values relate to their interests (Kerr, 1991). They cannot be allowed to become exhausted achievers who try to excel in everything, being "all things to all people." Throughout school, counselors need to help multipotential students to understand that a true passion for one or two activities and academic areas is preferable to a competitive urge to be the best at everything they try.

Olszewski-Kublius and Scott (1992) stated that economically disadvantaged, minority gifted students are especially in need of early encouragement, exposure, and access to information, yet are less likely to receive it. Some literature suggests that even a brief career counseling intervention can have a positive impact on career development with minority students, but it is essential to respect the worldview and values of the participants (Darou, 1987; Herring, 1990; LaFromboise, Trimble, & Mohatt, 1993; Lotta & Benally, 2005). For example, it is important for school counselors to understand that academic and career decision making may be more complicated for gifted students from some collectivist cultures, because they are taking more into consideration than just themselves and their nuclear family—they are also considering the needs of their extended family and community. For many gifted students, there is recognition that the life decisions they make affect more than just themselves—they also affect the family, extended family, and community, or "home" (Lotta & Benally). Consider the following scenario:

> Beverly is a 10th-grade Native American student at a small rural high school who is participating in a career intervention program. Beverly reports that her career goal is to become a dentist. While she is a multipotential student with high grades in all subjects, her vocational assessments and interest inventories are not at all consistent with those in the field of dentistry; rather, her profiles are much more consistent with creative writing or journalistic careers. When the school counselor explores this with her, Beverly acknowledges that she enjoys writing "more than anything else," but remains adamant that she will become a dentist, adding, "It's what my people need."

Although Beverly has the potential to pursue numerous career paths, her career goals are heavily influenced by what she perceives as being needed in her community. Part of attaining her career goal involves being able to "give back" in a way that benefits her family and community, as well as herself. Community responsibility is a crucial value in her culture that may even supersede her own personal goals or decisions. Being respectful of Beverly's worldview may change the way a school counselor approaches career guidance. For example, rather than having Beverly focus on making the "appropriate career choice" based on her abilities or profiles (a more traditional approach), it may be more culturally sensitive and appropriate to help her find a "fit" between her career interests, needs, and values. Beverly has expressed her value of community by her firm

commitment to provide much-needed services. The school counselor can respect Beverly's worldview by supporting her vocational decision while also helping her to find ways to also honor her other dreams; perhaps Beverly can find ways to become the dentist her community needs, and also balance her life by following her passion of writing in her avocational pursuits.

Myth 3: Gifted kids don't have any social or emotional problems—"They've got it all (and if they don't, they are smart enough to figure it out themselves)."

There is a misconception that gifted students do not have social and emotional needs. This assumption is dangerous because it means that these students do not receive the understanding and support to cope with their social/emotional struggles (Galbraith & Delisle, 1996; Kerr, 1991, Lovecky, 1993). Because gifted students may present as advanced in their cognitive abilities, it is often assumed that their emotional maturity matches their intellectual maturity. Even when it is recognized that gifted children may have social, interpersonal, or intrapersonal concerns, it may be assumed that they have intellectual abilities that provide certain coping advantages. This is the sentiment that gifted students should be able to "figure out" and manage any personal or emotional challenges that they may encounter on their own. Yet, gifted students do not always have the emotional development, life experiences, and skills to effectively cope.

While some have proposed that, overall, gifted children are better adjusted and have stronger self-concepts than regular students (Coleman & Fults, 1982; Davis & Rimm, 1989; Terman & Oden, 1951) and are socially and emotionally more mature than same-age peers (Colangelo et al., 2004), the literature and research on gifted children clearly show that gifted students *do* have social/emotional concerns. They may struggle with typical childhood and adolescent struggles, as well as additional social/emotional issues specifically related to their giftedness, including relationship issues, stress, perfectionism, and depression.

Before exploring some of the common social/emotional concerns of these students in more detail, we provide a theory of emotional development that may help the reader to understand the inner experience of gifted children.

Dabrowski's Theory of Emotional Development. One of the few psychological theories specifically focusing on giftedness and creativity is Dabrowski's Theory of Emotional Development, based on the work of Kasmirez Dabrowski. This theory emphasizes emotional and affective development in addition to cognitive development (Piirto, 1999). Dabrowski explored the notion of overexcitabilities (OEs), proposing that gifted children have greater capacities to respond to various stimuli (Piechowski, 1991), and that they may respond to even small stimuli more strongly and longer than would generally be considered normal (Tolan, 1999). These extreme intensities are thought to be innate and present from infancy, resulting from highly sensitive nervous systems (Blackburn & Erickson, 1986; Dabrowski, 1938, cited in Silverman, 1993; Tolan). The OEs are an abundance of energy and may be experienced in various areas, including sensual, imaginational, psychomotor, intellectual, and emotional. Highly gifted people tend to evidence all five of the OEs, but may "lead" with different ones (Tolan). Dabrowski's (1972) study of a group of gifted youth in Warsaw found considerable manifestations of OEs. Several studies of gifted youth have found significantly higher levels of OEs than those of nongifted students (Ackerman & Paulus, 1997; Dabrowski).

Sensual overexcitability. From a very early age, those with sensual OE experience a heightened sensory awareness. They derive great pleasure from experiencing the world through their senses, yet may also feel bombarded and easily overwhelmed by such stimulation (Silverman, 1993; Tolan, 1999). These children may be completely awed by the beauty of nature or have a powerful negative reaction to foul odors or bright lights.

Imaginational overexcitability. Imaginational OE is related to creativity and may be demonstrated through elaborate fantasies and daydreams, use of images and metaphors in thinking and communicating, and detailed visual recall (Silverman, 1993; Tolan, 1999). These students are inventive and may also have a tendency to blend truth with fiction and often possess a flair for the dramatic. As young children, they may have had an imaginary friend, and as adolescents they may be drawn to science fiction or fantasy. Because they tend to think in vivid images, it may be challenging and even frustrating for these students to communicate their thoughts and feelings verbally. Investigations have found that imaginational OEs tend to be present in artists and creative children (Piechowski, Silverman, & Falk, 1985) and are higher in gifted adolescents than in nongifted peers (Piechowski & Colangelo, 1984; Schiever, 1985).

Psychomotor overexcitability. Those with psychomotor OEs tend to be highly active, talkative, impulsive, competitive, and enthusiastic (Piechowski, 1991). As infants, they may have required less sleep. In case studies of young gifted students ages 4 though 6, psychomotor OE was noted in their high levels of enthusiasm, rapid speech, impulsive actions, and surplus of energy. These children may be misdiagnosed with Attention Deficit/Hyperactivity Disorder

(Schetky, 1981; Silverman, 1993). A notable difference is that children with psychomotor OE are able to sustain focused attention and concentration when they are sufficiently interested. Problems tend to arise when they are bored or feel that the activity or topic is not meaningful. It is important to note that psychomotor OE needs to be accompanied with other OEs in order to be considered significant and differentiate a gifted student from an average student (Piechowski & Cunningham, 1985; Silverman, 1993).

Intellectual overexcitability. The OE that is predominantly correlated with high intelligence is intellectual OE (Silverman, 1993; Tolan, 1999). This OE involves fervent curiosity, persistent intellectual effort and concentration, introspection, and analytical thinking. These youth develop the ability for abstract thinking early on and are often asking probing questions. It is also typical that they will have complex and highly developed moral reasoning and interest in theory. It must be noted that intellectual OE is not the same as intelligence (Piechowski, 1979). It is possible that someone who has a high IQ may not necessarily have an abundance of energy and intensity regarding learning, theorizing, and problem solving. Those who score high in intellectual OE are not always intellectually gifted. In a study by Piechowski and Cunningham (1985), artistically gifted adults scored just as high on intellectual OE as intellectually gifted.

Emotional overexcitability. Of all of the OEs, emotional OEs are central to the energies of the others (Tolan, 1999). Individuals with emotional OEs have intense feelings that are often evidenced from a very young age (Silverman, 1993). They are highly aware of their moods and emotional highs and lows, which may include intense feelings of joy, pain, guilt, self-criticism, and anxiety (Galbraith & Delisle, 1996; Silverman; Tolan). There is a depth and complexity to their own emotions as well as a heightened sensitivity to the emotional experience of others. In addition, there is a need for meaningful connections to other people or animals. These youth may have a profound concern with existential issues such as death and may also experience their emotions somatically such as a sense of having tension in their heart or stomach. There can be a tendency to become totally absorbed in thoughts, emotions, activities, or issues that matter to them. It is believed that the level of intensity and sensitivity of emotional response increases with the degree of giftedness (Piechowski, 1997). Higher levels of emotional OE have been found in gifted children, adolescents, and adults (Piechowski & Colangelo, 1984; Schiever, 1985; Silverman, 1983; Silverman & Ellsworth, 1980).

Children with sensual, imaginational, psychomotor, intellectual, and emotional OEs feel differently, experience the world differently, express themselves differently, and learn differently. They also have unique social and emotional needs related to their extraordinary sensitivities (Silverman, 1993). Experiencing the world with greater intensity than others can feel overwhelming, scary, and isolating. These youth are often on the receiving end of overt and covert messages from peers, adults, and society that they are overreacting or melodramatic. School counselors can be instrumental in helping these students understand, manage, and even celebrate their sensitivities and passions.

Common Social/Emotional Concerns for Gifted Students. An exhaustive description of possible social/emotional concerns experienced by gifted youth is beyond the scope of this chapter. However, we provide information from the literature about some common issues school counselors may encounter in their work with gifted students.

Relationship issues. Dating back to the work of Leta Hollingworth (1926), studies have found that the great differences in intellect between gifted and average peers often creates difficulty in establishing relationships. Webb, Meckstroth, and Tolan (1982) reviewed the major problems gifted and talented students have in peer relationships. Many difficulties gifted students have in peer relationships relate to their uneven, or asynchronous, development. Often, from the very beginning of elementary school, gifted young people's intellectual development outstrips that of their same-age peers to the point where they become "group deviants": they are simply too different intellectually to be accepted by their age-mates (Webb et al., 1982) and are often on the receiving end of negative nicknames such as "nerd," "dweeb," or "egghead" (USDE, 1993). These students tend to enjoy playing with older children, with whom they relate on a cognitive and humor level (Silverman, 1993; Webb, 1994). Webb et al. suggested that gifted children need several different peer groups that fit their different physical, intellectual, and social levels of development. They also pointed out that what adults consider to be satisfactory peer relationships may be very different from what the gifted child considers to be satisfactory. Pressuring gifted children to "fit in" makes them feel as if they must hide their gifts and their true selves. Too often, adults assume that a gifted child lacks social skills when the actual case is that the child has social skills, but chooses not to use them. Lovecky (1993) described gifted children as being particularly at risk for social ostracism, stating, "Many are more interested in following their own inner vision than in conforming in ways that will bring acceptance from peers. However, they are not always happy about the results" (p. 34). School counselors can help these students explore the process of their own decision making about social relationships. These students can benefit from

support for their decisions, while also being encouraged to examine the consequences of their choices.

Relationships and "fitting in" often become increasingly important to gifted girls as they enter adolescence (Fielder, 2005). Whereas their focus in lower elementary school may have been on academic achievement, the bright girl approaching middle school may quickly shift her focus to friendships, romantic interests, and acceptance by peers. It is at this point that self-esteem declines and the gifted female may begin to hide her giftedness, intentionally underachieve, and begin to engage in risky behaviors (Kerr, Foley-Nicpon, & Zapata, 2005). Bright girls, in particular, need consistent encouragement and support in resisting the intense pressures to fit in or evaluate themselves primarily in terms of their attractiveness or their relationships (Kerr, 1994).

Culturally diverse gifted students may have additional struggles with peer relationships and acceptance (Grantham & Ford, 1998). Research has suggested that racial/ethnic minority students in gifted programs often find that access does not always result in acceptance. Because of their underrepresentation in gifted education programs, minority students (especially those in predominantly White schools) are often in predominantly White gifted classes and struggle with feelings of social isolation and exclusion, which may have a negative impact on their cultural identity. Students in these environments report having to adopt new behaviors and styles of speaking in order to try and fit in with White peers. Even with these alterations, gifted minority students are often the targets of covert and overt acts of racism on the part of their White classmates.

Peer issues do not occur solely in relationships with White peers. Often, gifted racial/ethnic minority students also experience peer rejection within their own racial/ethnic social groups. Similar to the way in which gifted adolescent females are ostracized for "acting smart" (Kerr, 1994), gifted minority students that achieve academically are often accused by their peers of rejecting their own culture and "acting White" (Ford, 1995; Kitano, 1998; Kruger, 2004; Tatum, 1997; USDE, 1992). In a survey of 31 gifted Black females in a predominantly Black, low-income community, Ford found that 54% of participants had experienced being teased by peers for academic achievements. Moreover, nearly one third of the participants had been accused of "acting White," and approximately 28% stated that they did not think that people would be friends with kids who were smart. In her interviews with gifted African American women, Kitano noted similar results. Six out of the 15 women interviewed reported that, during the school years, doing well academically frequently led to peer conflict.

Stress. Gifted students often feel a great deal of pressure to achieve from parents, teachers, peers, administrators, and their community (Grantham & Ford, 1998; Kerr, 1991). For some gifted children, meeting others' expectations has become a way of life (Kerr, 1981a). Jim Delisle (1984), in his book, *Gifted Children Speak Out*, gave many examples of students' beliefs that others hold expectations of them that are too high. Many gifted students describe a cycle in which achievement is followed by expectation of higher achievement, which is then followed by higher achievement in a never-ending spiral, so that the student believes that no matter how much he or she may try, no attainment will ever be enough. Pressure can also be experienced from within when gifted students set their own internal standards too high (Kerr, 1991). Many gifted students seem to "raise the stakes" on their own, even when parents, teachers, and counselors assure them that their performance is excellent. In their attempts to meet the expectations of themselves and others, gifted students may face antagonism from peers for their achievement focus, thus adding to the potential for stress (Clinkenbeard, 1991; Grantham & Ford).

Another common source of stress in the lives of gifted students is overcommitment to school activities, which often begins in elementary school. Multipotential students, with multiple interests and skills, often seem to find themselves involved in nearly every extracurricular activity available (Kerr, 1981a). It can be difficult for these students to prioritize in order to make their lives more balanced. Decision making can be particularly challenging for the gifted student (Kerr, 1991; Webb, 1994). Often adults expect that gifted children can make difficult decisions simply because of their excellent reasoning abilities, not recognizing that they may have limited skills and life experience from which to make these decisions. If students are given choices beyond their capacity for decision making, they may react with avoidance, confusion, and anxiety.

Poverty is a contributing factor to stress for some gifted students and is often related to rates of substance abuse (Beauvais, Oetting, Wolf, & Edwards, 1989; Husted, Johnson, & Redwing, 1995; Yee et al., 1995) and depression (Husted et al.). Those students who are racial/ethnic minorities may have the added stress of minority status (Smith, 1985). This stress can place these students further at risk as they attempt to cope with potential racial discrimination, alienation, and social isolation, in addition to the internal and external pressures they feel related to their giftedness.

Prolonged stress can have an impact of physical, mental, and emotional well-being (Greenberg, 2004). Strategies for preventing stress and coping with stress can be crucial skills for gifted students to develop (Galbraith & Delisle, 1996). School counselors can help gifted students prevent

stress through strategies such as encouraging creative play and teaching students time-management and prioritization skills (Kerr, 1991). Discussion of both maladaptive coping strategies (e.g., withdrawal or alcohol/drug use) and adaptive coping strategies (e.g., relaxation training or changing cognitions) can empower gifted students to better manage stress within their lives. Gifted students can benefit from the guidance and support of school counselors as they develop healthy coping strategies and seek balance and meaning.

Perfectionism. Within the literature, perfectionism is a commonly described problem of gifted individuals from very young ages. (Kerr, 1991; Gallagher, 1990; Robinson & Nobel, 1991; Roedell, 1984). Webb (1994) stated that, in high-ability children, up to 15% to 20% may be significantly impacted by perfectionism. Kerr (1991) described perfectionism as a complex of characteristics and behaviors including compulsiveness with regard to work habits, overconcern for details, unrealistically high standards for self and others, indiscriminate acquiescence to external evaluation, and rigid routines. In comparison with their same-aged peers, gifted children often have the ability to perfectly carry out many tasks, especially cognitive tasks, expected of their age level. In this way, perfectionism becomes entrenched and part of the child's identity early on (Kerr, 1991, 1994).

Another potential contributing factor to perfectionism is extrinsic motivation (Kerr, 1991; Winebrenner, 2001). Gifted children whose abilities have been shaped by ever-increasing contingencies and who have been pressured into performing for points, grades, and awards soon lose a sense of ownership of their talents. An overemphasis on rewards can lead to less creative, more automatic behavior. A gifted child can develop perfectionistic behavior when he or she responds to all situations as an opportunity to gain "points." Gifted perfectionists tend to generalize their perfectionism to other areas of their lives, such as relationships and hobbies.

Gifted kids need help in overcoming the "fear of failure" (Kerr, 1994; Galbraith & Delisle, 1996), as well as the "fear of success." As early as elementary school, these students need encouragement to take risks and appreciate that true learning is an often frustrating struggle that takes effort (Winebrenner, 2001). Learning how to make mistakes can be one of the most critical skills a talented student can learn (Galbraith & Delisle). When gifted kids have opportunities to fail within a supportive environment, they can develop the skills necessary to "fail gracefully," make sense of the experience, learn from their mistakes, and persist in the task.

Related to the benefits of gifted students' learning how to make mistakes is learning how to tolerate frustration. Perfectionism can be related to asynchronous development, or uneven development in the rates of cognitive, emotional, and physical abilities (Silverman, 1993). One common example of this is the young elementary gifted students who become extremely frustrated when their limited physical coordination in writing with a pencil does not allow them to express their thoughts as neatly or quickly as their mind is working. They demand perfection, yet are not able to produce it in a way that meets their expectations. The school counselor can provide the necessary adult guidance in helping the gifted students in setting realistic goals and developing strategies for coping and problem solving, without compromising their ideals and goals (Roedell, 1990).

Some have asserted that perfectionism may also have positive aspects (Dabrowski, 1972; Robinson & Noble, 1991), stating that it can provide the driving energy toward achievement (Roedell, 1984). When understood and channeled appropriately, perfectionism can be used productively as a positive way to achieve excellence (Silverman, 1993). School counselors can help gifted students turn perfectionism from something that hinders their achievement and satisfaction into something that brings them success and pleasure.

Depression. Depression among gifted students is increasingly becoming a concern of parents and educators (Kerr, 1991). Many of the same situations that lead to stress for the bright child can also become precursors of depression. Kaiser and Berndt (1985) reported pervasive feelings of depression, anger, and loneliness in one eighth of the 175 gifted junior and senior high students in their study. Under conditions of prolonged stress, a student may gradually lose motivation, energy, and the will to go on. While the research is unclear whether gifted students are statistically at greater risk than average students for suicide, there is evidence that a high proportion of students who commit suicide are at least above-average students (Delisle, 1996; Kerr, 1991; Silverman, 1993). Some speculate that their heightened sensitivity and tendency toward perfectionism may place gifted youth at higher risk for suicide (Delisle, 1996).

One type of depression that seems to be unique to gifted students is a kind of premature existential depression (Webb et al., 1982). Existential depression occurs in gifted children and adolescents when their capacity for absorbing information about disturbing events is greater than their capacity to process and understand it. Second graders who are capable of reading news magazine accounts of war and pollution may understand the information but not be able to deal with their helplessness to do anything about it. As Hollingworth (1926) pointed out long ago, many gifted children feel trapped in a world created by adults that is somehow out of control. Some gifted students seem to experience existential depression as a result of having wrestled with concepts with

which even the wisest of adults have struggled, such as the meaning of life, the inevitability of death, and the beginning and end of the universe. Asynchronistic development, or the incongruence between the child's developmental stage and intellectual abilities, may play a part in existential depression (Silverman, 1993; Webb et al., 1982). A young person whose cognitive development is still "dualistic," that is, still perceiving the world in terms of absolutes such as right and wrong or good and bad, may be disturbed by reading and thinking about questions for which there simply are no right or wrong answers. Unable to resolve the ambiguity, the student lapses into anger and despair.

While it is clear from the literature and research that gifted students have a number of social and emotional concerns related to their giftedness, there can be a danger in attributing all of their struggles to giftedness. Many people hold a stereotype that because of their advanced abilities, all gifted individuals are so "different" that they are unable to relate to or connect with others and that they are difficult to deal with (Galbraith & Delisle, 1996). This may be the gifted child who seems to be in his or her own world, withdrawn and isolating. It may be the gifted student who is pegged as the "know it all"—constantly answering questions in class, easily frustrated with peers who don't "get it" (particularly in group activities), unreceptive to feedback, and even correcting the teacher. Or it may be the student who persistently asks the difficult questions that challenge the adult's expertise or authority. These students are often seen as contributing to their own social rejection, garnering very little sympathy from others. Perhaps the most dangerous concern about this misconception is that it can perpetuate the idea that gifted students' issues are solely a result of their intelligence, and therefore they cannot be understood or helped.

Recommendations for Practice

The preceding sections of this chapter have been designed to (a) increase your understanding of some of the most salient academic and social/emotional concerns of gifted and talented youth, and (b) familiarize you with some important research and strategies that can help guide the design and delivery of school-based interventions with this population. In the following section, we will focus in more depth on practical application of this knowledge, paying specific attention to suggested intervention strategies that address three key areas of concern for gifted and talented youth: (a) academics, (b) career planning, and (c) social/emotional needs.

Within each area of concern, we will concentrate on three primary roles that the school counselor can play, namely, (a) counselor, (b) consultant, and (c) advocate. Examples of each of these roles are provided in Table 34.1. It is important to note that these roles are consistent with those recommended by the ASCA in their position statement of gifted student programs (See Appendix A).

Addressing Academic Needs and Concerns

As we have discussed previously in this chapter, providing academic support and guidance is one of the most critical roles that the professional school counselor can play for the gifted and talented population because their academic needs are often not met within the context of the regular school program (Kerr, 1991; VanTassel-Baska, 1993b). Gifted students and their families need assistance in developing a course of study that will best meet their academic needs. In addition, they may be unfamiliar with available enrichment opportunities outside of the school setting that could supplement their school-based experiences. This may be especially true for those in rural settings. Four key ways in which the school counselor can provide academic support are (a) being knowledgeable about identification practices, (b) advocating for curricular interventions, (c) consulting with students and parents about academic planning, and (d) serving as a resource for enrichment options. Each of these will be briefly discussed. In addition, a summary of recommendations for addressing academic needs and concerns is provided in Table 34.2.

Understanding identification. As illustrated earlier, the process of identifying and assessing gifted and talented students is complex. Identification methods and qualifying

Table 34.1 Roles of the School Counselor Working with Gifted and Talented Youth

	Counselor	Consultant	Advocate
EXAMPLES OF INTERVENTIONS	• Providing individual and group counseling to address social/emotional needs	• Providing resource information to parents and teachers regarding specific academic and social/emotional needs	• Promoting use of appropriate criteria for assessment and identification
	• Facilitating developmental guidance programming focused on career exploration	• Serving as a resource regarding weekend and summer enrichment opportunities in the community	• Encouraging continued support for programs that address the specific needs of gifted and talented youth.

Table 34.2 Recommendations for Addressing Academic Needs and Concerns by Grade Level

	Elementary School	Middle School	High School
Be knowledgeable about identification criteria and processes for your school district and be prepared to advocate for students who may not "fit" the stated criteria.	*	*	*
Assist parents and families in understanding and negotiating the education system.	*	*	*
Assist gifted students (and their families) in developing academic decision-making skills.	*	*	*
Consult with parents and help advocate for challenging curriculum and academic interventions (e.g., acceleration, enrichment, differentiation) when appropriate.	*	*	*
Advocate for the use of culturally relevant curriculum in gifted programming.	*	*	*
Be able to recognize underachievement and intervene appropriately.	*	*	*
Serve as a resource for out-of-school Saturday programs and summer opportunities for gifted children.	*	*	*
Assist parents and school staff in determining appropriateness of early admission to kindergarten.	*		
Encourage gifted students to participate in Talent Search process and take necessary tests (e.g., SAT, ACT) to qualify them for Talent Search program participation.		*	
Help students begin a college planning time line and explore opportunities for preparing for admission (e.g., enrolling in high school–level classes, volunteer work)		*	*
Provide developmental guidance experiences, with topics such as time management, study skills, and course selection.		*	*
Assist in finding appropriate online courses.		*	*
Encourage AP classes; provide advocacy for admission into AP classes when necessary.			*
Encourage continued college preparation activities such as practicing the PSAT (10th grade), taking the PSAT (11th grade), college visitations, and review of college reference books.			*
Assist gifted students in exploring, applying for, and deciding about college options.			*

criteria are variable and often fail to create gifted and talented populations that are diverse and representative of the school as a whole. Consequently, in order to best meet the needs of *all* gifted students within the school, it is critical that the school counselor (a) have a solid understanding of how giftedness is defined within his or her school district and (b) advocate for assessment practices that are inclusive of cultural diversity, such as a multiple criterion system (ASCA, 2005).

It is also important that the school counselor be familiar with the ways in which students from different cultural backgrounds may manifest their giftedness, as well as the impact that other issues, such as learning disabilities, language barriers, or family circumstances, might have on how a student's giftedness is expressed. For Anita, it was critical for her school counselor to understand that her English language proficiency and significant family responsibilities were contributing to her uneven academic performance and even masking her mathematical giftedness. By being sensitive to the characteristics of diverse gifted populations, the school counselor can help to ensure that *all* gifted students have the opportunity to access the specialized services that they need (Evans, 1997; Mendaglio, 1993).

Curricular approaches. Some of the most important tools that a school counselor can utilize to promote the positive academic experience of gifted students are curricular interventions, such as acceleration, enrichment, and differentiation. The appropriate use of curricular modifications plays a critical role in ensuring that gifted and talented students stay engaged in their academic experience. The school counselor must be informed about intervention options in order to effectively support gifted students, their parents, and their teachers in the design of appropriate academic programs.

Academic planning. Supporting gifted students with academic planning is vital to ensuring that they have access to the most appropriate and engaging programs available (VanTassel-Baska, 1993b). As you have learned in this chapter, underachievement and dropout are salient issues for the gifted and talented student population. Effective academic planning serves an important preventative function in addressing this issue. Academic planning can occur in individual settings (e.g., meeting with students to discuss their course schedules) or group settings (e.g., talking with an eighth-grade accelerated math class about high

school course selection options). Three key questions for the school counselor to keep in mind when planning with a gifted student are

1. What classes will allow this student to feel engaged and challenged, academically?
2. What classes are essential for allowing this student to keep many doors open regarding higher education options and career interests?
3. What classes might be needed to help this student develop in important interest and skills areas in which he or she is less proficient?

Many gifted students are multipotential and have the ability to be successful in multiple areas. Consequently, they may have difficulty with deciding how to pursue diverse interests and make choices about academic courses (Silverman, 2000; Kerr, 1991). The school counselor can address this issue by helping gifted students develop academic decision-making skills. This could involve helping the student clarify values, set goals, and establish priorities. In addition, the school counselor could assist the student in finding ways to pursue some of his or her interests outside the school setting through extracurricular involvement and summer programs.

In contrast, some gifted and talented students may underestimate their ability in certain areas and intentionally choose less rigorous classes, such as girls not pursuing or persevering in math- and science-related curriculum (Kerr, 1994). Peer pressure and concerns about social acceptance can also cause gifted students to make inappropriate course choices. In both of these situations, the school counselor can provide support in working through these concerns and encourage the student to make decisions that will prevent them from foreclosing on future opportunities.

Enrichment resource. As previously mentioned, it may not be possible to meet all of a gifted student's academic interests within the school setting. In these instances, the school counselor can act as a valuable resource for enrichment opportunities, such as summer programs, weekend workshops, and online courses that are available outside of school. These extracurricular options serve an important function in allowing gifted students to have experiences (e.g., interest exploration, skill development) that their school environment does not provide, and may be particularly valuable for gifted students from low-income (Yee et al., 1995) and rural schools (Benbow et al., 1992; Luhman & Fundis, 1989).

School counselors can also facilitate another kind of enrichment opportunity—mentorships. A mentorship allows the gifted student the opportunity to work one on one with an individual, providing exposure to and information about a certain area of interest (Silverman, 1993). The mentorship relationship can support the gifted student in identifying, understanding, and taking pride in his or her greatest strengths and passions (Kerr, 1994; Schatz, 1999). In addition, mentorships have the potential to enhance self-esteem, career development, and social/emotional growth. Establishing a mentor relationship can be especially valuable for gifted students who feel disenfranchised by school, permitting them a chance to see others who have succeeded despite the obstacles (Van-Tassel-Baska, 2003).

Addressing Career Planning Needs and Concerns

The provision of career exploration and planning support is another important service that school counselors can offer their gifted and talented students. Two key ways in which the school counselor can address the career concerns of gifted and talented students are: (1) providing early access to career planning services, and (2) incorporating personality needs and values to the career decision making process. Both of these will be briefly discussed below. In addition, a summary of recommendations for addressing career planning needs and concerns is provided in Table 34.3.

Early access to career planning. As we reviewed previously, career counseling is a critical service for gifted students and often needs to happen at an earlier stage. Because of their developmental advancement, gifted children begin to be concerned about vocational choice much earlier than their peers. School counselors can encourage discussion and exploration of various careers, even with elementary school students. It can also be useful to involve parents in the discussion about the student's dreams and goals.

Incorporating personality needs and values. Multipotentiality, as we have explored, has a profound impact on career planning for gifted students. These students have interest and ability in many career fields, thus making the decision to pursue a specific career complicated. As Silverman (2000) noted, "When one is capable in many areas, aptitude is an insufficient criterion for selecting a career" (p. 215). Career guidance can be more effective in meeting the special needs of gifted students by looking beyond abilities and vocational interests alone, and incorporating personality needs and deeply held values (including cultural values). This model, called Values-Based Career Counseling (Kerr & Erb, 1991; Kerr & Kurpius, 2005) can help gifted students navigate the often confusing and complex

Table 34.3 Recommendations for Addressing Career Planning Needs and Concerns by Grade Level

	Elementary School	Middle School	High School
Provide realistic exposure to the world of work. Encourage parents to share information about their work and expose gifted students to diverse career options.	*		
Encourage career fantasies through dress-up and play.	*		
Encourage focus on activities that require goal setting and follow-through (class projects, achievement clubs, etc.).	*		
Use biographies of eminent people as primary career education material. Facilitate book discussion groups centered around the lives of eminent people in science, the arts, education, government, and entertainment.	*		
Help teachers and parents evaluate skills, talents, and interests carefully in order to help gifted students understand possible areas of greatest interest.	*		
Help gifted students discuss the meaning and value of work.		*	
Discuss family, cultural, and community values pertaining to work.		*	
Assist students in accessing career exploration opportunities such as volunteer work, job shadowing, and informational interviews.		*	
Help gifted students set priorities and make choices about extracurricular interests to prevent over-involvement.		*	
Help student plan a solid curriculum of course work in order to ensure against inadequate preparation for a later career choice.		*	*
Provide appropriate vocational testing for interests, personality characteristics, aptitudes, and values.			*
Encourage more extensive career exploration through volunteer and paid work experiences, internships with professionals, and visits to college classes in subjects of interest.			*
Provide values-based guidance emphasizing choosing a career that fulfills deeply held values. Understand the role that culture might play in shaping values.			*
Encourage nonconformist, nonstereotyped career choices.			*

process of making vocational decisions and help them to find career paths that have personal meaning for them. A values-based career intervention helped Beverly find ways to balance her dreams and pursue her passion, while also honoring her career goal and cultural values.

Addressing Social/Emotional Needs and Concerns

Throughout this chapter, we have provided literature and research that bring to light the importance of providing support to address social/emotional needs of gifted and talented students. School counselors will encounter gifted students who are struggling with concerns such as interpersonal issues with peers, as well as intrapersonal challenges such as stress, perfectionism, and depression. Gifted students need appropriate support in these areas. In her edited text *Counseling the Gifted and Talented,* Silverman (1993) provided a developmental model for counseling the gifted. This model, grounded in the unique shared traits of gifted and talented individuals, is designed to help the counseling professional in creating appropriate interventions for this population. Silverman described these interventions as "life preservers," necessary for "preventing alienation, depression, underachievement, and damage to their self-esteem" (p. 51). She suggested that, ultimately, counselors can help gifted students strive to live lives deeply imbued with immutable values, have the wisdom to choose the path of integrity, have the compassion to choose the path of service, and have the courage to become their best selves in the face of a world that often settles for less.

School counselors may believe that they have little time for social and emotional counseling for gifted students. However, a little attention to these special needs can go a long way toward keeping gifted students balanced and focused in their lives. Four key ways in which the school counselor can provide social/emotional support are (1) consulting with parents and teachers about how to best meet the social/emotional needs of their gifted and talented students, (2) providing individual counseling services, (3) providing group counseling services, and (4) serving as a resource for social enrichment opportunities.

Table 34.4 Recommendations for Addressing Social/Emotional Needs and Concerns by Grade Level

	Elementary School	Middle School	High School
Help parents and teachers understand asynchronous development and other social and emotional needs.	*	*	*
Act as a resource; make appropriate referrals when family or mental health counseling outside of school is needed.	*	*	*
Help students develop and maintain good peer relationships.	*	*	*
Encourage emotional expression through writing, art, and music.	*	*	*
Provide individual and group counseling to address social and emotional concerns.	*	*	*
Create prevention strategies—in-services for teachers, support groups for students—to support populations at risk of underachievement (such as adolescent girls, and African American adolescents) in maintaining their involvement in academically rigorous classes.	*	*	*
Encourage "failing gracefully" and finding meaning in making mistakes.	*	*	*
Teach stress-management strategies.	*	*	*
Use bibliotherapy; develop library of books with gifted individuals as protagonists.	*	*	*
Honor and encourage their dreams and goals.		*	*
Help students negotiate concerns with teachers and parents.		*	*
Facilitate the promotion of self-esteem and self-efficacy.		*	*
Facilitate the development of cultural identity.		*	*
Foster resiliency (e.g., through relationships with supportive adults, friendships with other gifted students, and participation in extracurricular activities).		*	*
Support students in individuation process.			*
Facilitate mentorship relationships.			*

Each of these will be briefly discussed. In addition, a summary of intervention strategies for addressing social/emotional needs and concerns is provided in Table 34.4.

Consulting with parents and teachers. The school counselor may be the first person parents approach with questions or concerns about their gifted child. Teachers may also seek consultation with the school counselor regarding social/emotional issues that they observe within the classroom setting or find are having an impact on academic performance. Both parents and teachers may need information about how to recognize and understand various social/emotional issues from the asynchronous development of the gifted kindergartner to the existential depression of the high school sophomore. School counselors may also need to provide referral information for outside support if additional resources, mental health support, or family counseling is needed.

Individual counseling. Gifted students may seek support from the school counselor for a variety of reasons, but it is unlikely that they will explicitly state that they need help "dealing with their giftedness." This makes it all the more important for the school counselor to be aware of the various ways giftedness may be a contributing factor when conceptualizing student concerns and considering possible interventions. Within the individual counseling context, there are opportunities for the student to explore *what it means to them* to be gifted. This may involve helping the student understand common experiences and struggles of gifted students or exploring how giftedness is incorporated into their overall identity. These general conversations can begin as early as elementary school. There are also opportunities to provide interventions for more specific issues they may be facing, such as concerns over peer relationship, stress, or depression. In individual counseling, Matt benefited from learning about and discussing how his emotional OEs impacted how he experienced his world, thereby helping him to gain self-understanding and self-acceptance.

Group counseling. It does not typically occur in a school day that gifted students are able to group together and talk about nonacademic concerns (Colangelo & Peterson, 1993). Providing gifted students with the opportunity to meet in a group setting gives them a chance to share their thoughts, feelings, and concerns with peers who may be more understanding and accepting. When facilitated by a school counselor who is sensitive to their social/emotional

concerns, it creates a safe space for these students to share their fears, struggles, and dreams and to seek support from others who identify with what they are experiencing. Group counseling may also be more culturally appropriate for those gifted students who come from a cultural background that is more collectivist. Because some cultures tend to value collaboration over an individual focus, it has been proposed that interventions in a group setting may be particularly effective with these adolescents in order to promote confidence, self-esteem, and identity (Aponte, Young Rivers, & Wohl, 1995). Within a group setting, Jackie demonstrated her leadership skills and was able to discuss her frustrations with class curriculum that was not challenging or meaningful. She was also able to share her concerns about being accused of "acting White" for academic achievement with other gifted minority girls who had faced similar situations and in so doing found the support and encouragement she needed to overcome these pressures.

Potential topics for counseling groups are endless and can be adapted for different developmental levels: gifted elementary students may benefit from discussions about peer relationships; middle school students may explore underachievement; gifted high school students may share career hopes and dreams as part of college planning. One group counseling approach that has been shown to be especially effective in working with this population is bibliotherapy (Silverman, 1993). In her book *Counseling the Gifted and Talented*, Silverman recommended a list of books dealing with gifted students as protagonists that can be used as a springboard for discussing challenges that students experience.

Social Enrichment Opportunities. Group experiences do not have to be limited to the school setting. Many students note the important role that outside activities for the gifted and talented can play in their social and emotional well-being. Even programs with an academic focus can provide gifted students the chance to engage in social relationships with their intellectual peers. School counselors play an important role in providing gifted students and their parents with information about such opportunities as weekend or summer enrichment programs, Midwest Talent Search, or mentorship programs.

Future Directions

Throughout this chapter, we have shared information and research about a frequently misunderstood and often underserved population within our schools. The numbers of counselors who are interested and trained in the needs of gifted and talented are growing. The Guidance and Counseling Division of the National Association for Gifted Children (NAGC) has seen extraordinary growth in its membership, and more teachers are reaching out to counselors for advice and support for their gifted students (Mahoney, 2005). It is likely that as counselors learn more about this population, they will increase their involvement in this professional area. Counselors should consider becoming involved in this division, as well as seeking opportunities at the American Counseling Association to gather with other counselors to discuss the needs of gifted students. The NAGC Web site (www.nagc.org) provides a wealth of additional information and resources that are valuable to the school counselor.

In addition, the growth of guidance laboratories at the university level has increased the knowledge and practice with gifted and talented. Guidance laboratories now operating at major universities include the Nebraska Guidance Laboratory for Gifted at University of Nebraska–Lincoln, the Iowa Counseling Laboratory for Gifted at the Belin Blank National Center for Gifted and Talented at the University of Iowa, and the Positive Psychology Laboratory at the Center for Psychoeducational Services at the University of Kansas. Special guidance laboratories for girls and for boys have been developed at Arizona State University with the sponsorship of the National Science Foundation. It is likely that university-based counseling programs for gifted will continue to be developed, and counselors should check with their local school of education or college counseling center for special programs for gifted and talented students.

As research continues on the special needs of gifted and talented, it is likely that more attention will be paid to such topics as dual exceptionalities, including gifted attention deficit disorder, gifted bipolar, gifted Aspergers/autism, and gifted personality disorders (Webb et al., 2005). In addition, it is likely that issues of gifted and gay (Cohn, 2003) and giftedness and gender will rise in importance (Kerr & Cohn, 2001). A new generation of bright students who have been raised in times of national crisis and war is coming of age, and the impact of these events on this sensitive and complex population is unknown.

Pfeiffer (2003) surveyed authorities in the field of gifted, asking their perspectives on current trends, concerns, and future directions. The experts in the study most frequently reported the continuing need to reach a consensus on how to define and identify giftedness, concern about how to increase the identification of gifted minority students, and the importance of translating the research on meeting the needs of the gifted and talented into practice. Furthermore, these veterans of the field expressed a need to "build a more compelling case for the value of supporting one of America's most precious resources—its gifted children" (p. 161).

Appendix A

American School Counselor Association (ASCA) Position Statement: Gifted Student Programs

The Professional School Counselor and Gifted and Talented Student Programs. (Adopted 1988; revised 1993, 1999, 2001)

ASCA Position

The professional school counselor assists in providing technical assistance and an organized support system within the developmental comprehensive school counseling program for gifted and talented students to meet their extensive and diverse needs as well as the needs of all students.

The Rationale

An organized support system throughout the formative years is imperative for such students to be able to realize their potential. A part of this support system is participation in a school counseling program that meets the extensive and diverse needs of the gifted and talented students.

The Professional School Counselor's Role

The role of the professional school counselor in gifted and talented programs may be as follows:

1. Assisting in the identification of gifted and talented students through the use of a multiple criterion system utilized in their school district, which may include
   - Intellectual ability
   - Academic performance
   - Visual and performing arts ability
   - Practical arts ability
   - Creative thinking ability
   - Leadership potential
   - Parent, teacher, peer nomination
   - Expert evaluation
2. Advocating for the inclusion of activities that effectively address the personal/social and career development needs, in addition to the academic needs of identified gifted and talented students
3. Assisting in promoting understanding and awareness of the special issues that may affect gifted and talented students including
   - Underachievement
   - Perfectionism
   - Depression
   - Dropping out
   - Delinquency
   - Difficulty in peer relationships
   - Career development
   - Meeting expectations
   - Goal setting
   - Questioning others' values
4. Providing individual and group counseling for gifted and talented students, as warranted
5. Recommending material and resources for gifted and talented programs and for teachers and parents of gifted and talented students
6. Engaging in professional development activities through which knowledge and skills in the area of programming for the needs of the gifted and talented are regularly upgraded

Summary

Gifted and talented students come from many backgrounds, and their special abilities cover a wide spectrum of human potential. Specifically planned educational experiences can greatly enhance the continued development of gifted and talented persons. Professional school counselors work in a collaboration with other school personnel to maximize opportunities for these students. The professional school counselor is an integral part of the educational team that delivers a comprehensive school counseling program to meet the needs of all students (ASCA, 2005).

XXXV
CULTURAL IDENTITY ENHANCEMENT STRATEGIES FOR CULTURALLY DIVERSE YOUTH

HARDIN L. K. COLEMAN AND SARA CHO KIM
University of Wisconsin–Madison
A. YANG
University of Minnesota–Twin Cities

Introduction

Over the past decade, culminating with passage of the *No Child Left Behind* (NCLB) legislation, the focus of the educational establishment has been on academic achievement as measured by performance on high-stakes examination. The American School Counselor Association (ASCA) has aligned with this focus through the development of national standards designed to facilitate the academic accomplishment of students. As Coleman (Chapter 4, this volume) has suggested, student academic accomplishment is not achieved through a singular focus on the acquisition and mastery of academic content. Despite the fact that not all students go on to attend 2- or 4-year institutions of higher education, there is substantive evidence that student academic accomplishment is facilitated by a host of nonacademic factors (Coleman, in press). As has been suggested elsewhere in the handbook (e.g., see Hage, Schwartz, & Barnett, Chapter 25, this volume), the singular focus on academic content reduces a focus on the emotional development of children, which is a key factor in performance. The central focus of this chapter is both on the role that cultural identity plays in facilitating academic accomplishment and to provide school counselors with an approach to enhancing cultural identity, which they can integrate into their developmental guidance program.

A review of the literature suggests that a positive view of one's culture and ethnicity and developing a healthy cultural identity is important to academic success and is predictive of psychological adjustment (Bernal, Saenz, & Knight, 1991; Coleman, Norton, Miranda, & McCubbin, 2003; LaFromboise, Coleman, & Gerton, 1993; Phinney, 1991, 1992; Phinney & Kohatsu, 1997; Roberts & Romero, 1999; Taylor, Casten, Flickinger, Roberts, & Fulmore, 1994). A significant task of early and middle adolescence developmental growth focuses on forming cultural identities (Manning, 1999/2000). Oftentimes, culturally diverse adolescents find themselves living in two very different cultures and struggle with developing an integrated sense of cultural identity (Coleman et al., 2003).

Studies on the general development of adolescents help us understand the biological and innate processes that are unique to each individual; however, less research has been devoted to understanding the impact of environmental and psychosocial factors on the identity development of culturally diverse adolescents. Culturally diverse adolescents, who face difficulties with adjustments to the school environment, are too often referred to as "at risk" by teachers and school counselors. Issues that many do not take into account are the multiple factors with which many of these adolescents have to contend with, such as cultural identity development, navigating multiple contexts, language, and various familial and social expectations that are too often different from the expectations of school. We suggest that addressing these concerns is a developmentally

appropriate focus for a middle school counseling program. Integrating these conversations into classroom guidance, small group interventions, and support to the curriculum development in academic courses is an important role that a school counselor can play. This chapter will provide explicit examples of what such a curriculum can look like for African, Latin, and Hmong descended students.

Thernstrom and Thernstrom (2003) and others (Bok, 2003; Ferguson, 2004) have noted that the achievement gap between African Americans, Latinos, and Asians is unacceptably large and continues to grow. It can be argued that in the middle school years the structure of the curriculum begins to separate children based on perceptions of their aptitude and motivation to do higher level math, leading to disparities in academic achievement. This process creates an implicit (and sometimes explicit) tracking system. As Thernstrom and Thernstrom have identified, this tracking system leads to systematic segregation within these classes by race and, historically, by gender (Denbo, 2002; Oyserman, Gant, & Ager, 1995). As this segregation increases with tracking, there is a greater chance of ethnic minority adolescents losing interest and potentially dropping out of school (Choi, Harachi, Gilmore, & Catalano, 2005). As Coleman (2006) has suggested, it is vital that we identify those resilience factors that help culturally diverse youth overcome the obstacles to their academic accomplishment and implement processes to facilitate the acquisition of these resilience factors among these youth. The purpose of this chapter will be to show how cultural identity may be one of those factors and give examples of how to facilitate its acquisition among particular populations. This chapter contributes to our understanding that a key role of a school counseling program for middle school adolescents is helping them understand their cultural identity as they prepare to find their place in society. In this chapter, we will focus on ethnic identity, but believe that similar activities to enhance gender or class identity are equally important. Grounded in theory, this chapter discusses the relationship among cultural identity, psychological adjustment and development implications, and culture specific interventions for cultural identity enhancement. Cultural identity and ethnic identity will be used interchangeably in this article. The rationale is that minority individuals in the United States may develop an ethnic identity but because of the influence of American society the term cultural identity is more appropriate.

In an attempt to address the multiple factors influencing culturally diverse adolescents, an integration of literature from counseling and developmental psychology, positive psychology, and cultural identity theories is provided for insight in constructing culturally sensitive strategies for optimal development in culturally diverse adolescents. In an effort to decrease the achievement gap along racial lines and to promote healthy cultural identity development, intervention programs tailored to specific cultural groups are discussed, with an in-depth look at one specific school-based intervention created by the authors. As noted by Harvey and Hill (2004), the model for the program, which can be tailored to specific cultural groups, focuses on the strengths and assets of adolescents to build on cultural values and self-awareness. Suggestions for further research on cultural identity enhancement are offered.

Cultural Identity Research

Research on cultural identity development has proliferated over the past three decades. In the past 20 to 30 years, there has been tremendous growth in the number of theoretical and empirical studies examining the process of cultural identity development (Parham & Helms, 1985; Phinney, 1990; Cross, 1991). Terms such as *ethnic identity development, racial identity*, and *multiculturalism* are included in this rapidly growing movement to understand the meaning and influence of culture in the lives and well-being of individuals. A number of studies have examined specific ethnic and racial groups based on the development of major racial categories of African Americans, Asian Americans, and Latinos. Upon closer examination, much of this research has focused on young adult or college-aged populations (Cross; Parham & Helms). There has been less focus on younger cohorts of children and adolescents (Phinney, 1990; Quintana, 1998).

A focus on the middle school years, adolescents between the ages of 11 and 14, is crucial. During this significant stage in their lives, culturally diverse adolescents are up against challenges that other adolescents from the dominant culture are less likely to face. Research has suggested that this is a time when adolescents are starting to develop a coherent sense of their cultural self. Historically, a monocultural perspective has dominated that study of human development where the focus has been on one's sense of self-identity (Erickson, 1968). More recent perspectives believe that one's sense of self is deeply integrated into one's contextual relationships (Bronfenbrenner, 1979). It is, at this time, important that systematic interventions need to be implemented to facilitate the development of one's sense of cultural self.

Positive Psychology

The field of positive psychology informs us of the various approaches offered through the examination of optimal functioning: character development, strength-based intervention programs, asset building, and core values devel-

opment. In recent years, the concept of focusing on the strength-based model, as opposed to a deficit-based model was reinvigorated by Seligman and associates (Seligman, 1999; Seligman & Csikszentmihalyi, 2000). Seligman suggested that the field of psychology must shift the focus of the field to promoting a stronger "I–We balance" in which the family and the community are also included. Too often, the value of individualism in the dominant culture makes it easy to ignore the other important variables of connecting with family and community in creating conditions for optimum functioning (Seligman).

An extension of the field of positive psychology has focused on developing interventions for adolescents based on the premise of strengths and assets. Recent scholars have attempted to create a strength-based intervention model to be used with adolescents (Smith, 2006). Smith emphasized the importance of integrating cultural values in developing strength-based interventions for at-risk adolescents. By connecting adolescents to their culture, they are in effect extending the bond with family and community. As noted earlier, by creating a balance of the collective or "I–We balance," culturally diverse adolescents can strengthen their ties to their native culture and ultimately feel a stronger sense of self grounded in their bicultural identity (Seligman, 1999).

Cultural Identity Development

In the field, a widely accepted definition of *cultural identity* has been provided by Jean Phinney (2003). She used the term *ethnic identity* whereas we will use *cultural* and *ethnic identity* interchangeably in this chapter. Phinney stated that cultural identity development is a dynamic, fluid understanding of self and ethnicity. The development of cultural identity involves a process whereby an individual develops a sense of self based on at least race, ethnicity, culture, religion, language, or kinship. It is important to note the multiple factors that influence identity and the dynamic nature of identity formation.

Adolescents from ethnic minority groups find themselves living in two very different cultures and struggle to develop an integrated sense of cultural identity (Coleman et al., 2003). Many children want to belong with their ethnic community and at the same time they want to become mainstream Americans. They experience much confusion and ambivalence from feeling stereotyped by mainstream Americans in their community and schools and feeling culturally isolated from their original culture. At home they cannot talk about school and social activities because parents may not understand them, and at school they cannot talk about their cultural traditions to Americans who would not understand them (Trueba, Jacobs, & Kiron, 1990). They might even possibly risk being ridiculed for certain traditional practices.

Phinney (1991) suggested that identification with both one's own group and the mainstream culture is predictive of psychological adjustment. Bernal and colleagues (1991) went on to further suggest that positive ethnic identity with one's culture may promote academic achievement by acting as a cushion for the psychological stresses experienced by minority adolescents in school. Other researchers have consistently shown the positive relationship of ethnic identity to self-esteem (Phinney, 1992; Phinney & Kohatsu, 1997; Roberts & Romero, 1999) and school involvement (Taylor et al., 1994).

When considering the identity development of culturally diverse adolescents, an examination of the dominant culture and the ethnic culture is necessary. LaFromboise et al. (1993) noted that students have to learn to cope in two different cultures to succeed academically. They identified seven elements of bicultural competence: (1) knowledge of both cultures, (2) positive attitudes toward both groups, (3) communication competency, (4) role repertoire, (5) social support systems in both cultures, (6) bicultural efficacy, and (7) groundedness. These competencies are more descriptive of adults navigating in two (or more) cultures; two of the competencies are developmentally appropriate for adolescents, that is, knowledge of both cultures and positive attitudes toward both groups. Coleman (1995) also suggested learning about positive qualities that are core to the culture, an emphasis on group solidarity, and learning to negotiate dominate culture from a position of strengths as foci for cultural specific interventions.

Programs for Enhancing Cultural Identity Among Culturally Diverse Adolescents

Based on LaFromboise et al.'s (1993) assertion that bicultural competence facilitates successful adaptation to the risks ethnic minorities face living in a European American dominated society, Bass and Coleman (1997) developed an effective program for enhancing cultural identity within African American adolescents. Since that time, Coleman, Yang, and Cho Kim (2004) and de la Luz and Coleman (2003) have developed similar program for Hmong and Hispanic adolescents, respectively.

Bass and Coleman (1997) hypothesized that one source of academic underachievement in African American adolescents was that they were not grounded in their culture of origin but were acculturating to dominate society where their culture of origin was devalued, leaving them to feel like second-class citizens. In other words, they were not

learning the positive values of their own culture as they were asked to perform within a second culture. To test the hypothesis, they developed a 20-week school-based intervention called the *Kwanzaa* program (see Appendix A)**,** which was designed to initially ground the participants in Afrocentric ideology and then work with them to apply that perspective within a predominately White institution. They found significant improvement in the participants' GPAs and social performances as measured by frequency of detention and teacher evaluation of in-class behavioral performance. The findings in this intervention reinforced three assumptions: (1) that cultural identity is an important factor in adolescent development, (2) that middle school is a critical time to address these developmental issues, and (3) that using a group to address these issues has developmental and practical value.

Yang, Cho Kim, and Coleman (2004, see Appendix B) and de la Luz and Coleman (2003, see Appendix C) have developed similar programs for Hmong and Hispanic adolescents, respectively. Manuals were developed using LaFramboise et al.'s (1993) model of bicultural competence as the basis for cultural identity enhancement and the common elements that promote positive cultural identity. The interventions are based on the notion that culturally diverse adolescents gain knowledge of American culture and history from school and their daily interactions with the dominant society (directly or through the media) but often lack knowledge of their own culture and history of origin. The best strategy for understanding how their culture of origin functions is to identify the core values and traditional practices of that culture. Culturally diverse adolescents will need to know the positive aspects of these core values and be able to relate these concepts into their daily lives so that they can negotiate the dominate culture from a position of strength, while group solidarity of members in the programs acts as a support network.

The manuals were developed with the assumption that each culture has a set of core values that separate it from others. It is not that these values are not present in other cultures; it is that there is a set of values that members of the culture identify as representing their culture. The first step for each program was to identify those core values. For each program, those values were identified differently. For the African American program, the decision was made to use the *Kwanzaa* principles developed by Karenga (1980). For the Hmong program, *Calm Heart*: *Ua Siab Tus Yees*, given the lack of written history, the authors interviewed Hmong elders in the Midwest to gain a sense of what these elders understood to be the Hmong core values (Coleman et al., 2004). For the Hispanic program, *Fortaleciendo Nuestras Raíces: Strengthening Our Roots,* the author completed an extensive review of the counseling and values literature concerning Latino values (de la Luz, 2003; de la Luz & Coleman, 2003). Once the values were identified, a manual for each group was developed to share these values with adolescents from that particular culture.

The *Kwanzaa* program was the beta model. It was created and tested first. The subsequent programs based their structure on the success of the *Kwanzaa* program. Each session was designed to teach about a particular value, give the participants an opportunity to discuss how that value was, or was not, operational within his or her life, and how knowing about this value might affect his or her decision making. Working within the group format helped to create safety and build group cohesion; however, these factors alone did not change behavior. Bass and Coleman (1997) determined that it is necessary to directly discuss ways in which one can express his or her cultural values within the dominate society in order to facilitate change. The results support LaFromboise et al.'s (1993) supposition that bicultural efficacy, the confidence to act in a bicultural manner, is an essential element in bicultural competence. The final and most significant factor in the development of the manuals involved creating activities within the group that would allow the participants to practice a culturally specific action that integrated the value under consideration.

Traditional models of identity development (e.g., Erickson, 1968) suggested that the task of middle adolescence is to develop an autonomous and integrated sense of self. We would suggest that this is the appropriate task within a homogenous setting where one's cultural framework dominates the values and behaviors within the significant institutions (e.g., schools) with which the adolescent interacts. If the school curriculum in which one is being enculturated represents your values and your history, provides models of how people like you have been successful, and uses the language of your home to facilitate your learning, then accomplishing the task of demonstrating how you will represent this culture as an individual becomes the appropriate task. If you come from a cultural group that is not central to the values and behavior of a particular institution such as school, then the adolescent identity development task becomes more complex. We suggest that the task for minority students (and others who are not reflected in the core curriculum such as gay individuals) changes from how to develop an autonomous and integrated sense of self and personal agency to how to develop a positive, connected, and integrated sense of cultural self within a heterogeneous setting. We are advocating that middle school counselors learn to explicitly address this developmental task within their counseling programs through the use of small culturally specific groups that focus on cultural identity development.

To give an example of how this process can work, we will describe the program for Hmong adolescents in more detail.

Calm Heart: Ua Siab Tus Yees

Interviews were conducted with Hmong elders and compared with existing literature to determine core Hmong values. Five general core values were identified: (1) respect, (2) care, (3) hard work, (4) ethics, and (5) wisdom. As an example, *wisdom* is defined as choosing and acting in culturally appropriate ways to accomplish tasks and responsibilities in the best interests of your life, family, and future; and wisdom is a life-long process that includes but is not exclusive to learning in school; from family, friends, and work; and through society's examples. Based on these core values, the *Calm Heart: Ua Siab Tus Yees* program is created to teach Hmong youth about these values in a culturally relevant manner (Coleman et al., 2004; Yang, Cho Kim, & Coleman, 2005).

This program incorporates various domains of an adolescent's life—peer group, community, and family members—to facilitate an understanding of their cultural identity. The goals of the program encourage the development and utilization of a positive ethnic orientation as a coping strategy for managing in a pluralistic society (Coleman, 1995; Tajfel & Turner, 1979) and to increase developmental assets (Hutchinson, 1997; Koltyk, 1997) within ethnic minority adolescents. Evidence from previous studies shows that a positive cultural identity may promote academic achievement by acting as a cushion for the psychological stresses experienced by minority adolescents in school (Bernal et al., 1991). As suggested by Coleman, this is achieved through teaching and facilitating the learning of positive qualities that are core to the culture (in this case, the five core Hmong values), an emphasis on group solidarity, and strategies for negotiating the dominant culture from a position of strength. The desired outcomes are to strengthen adolescents to become more engaged in school, home, and their community.

The program was developed with the assumption that Hmong culture has a set of core values separating this culture from others. Values guide how a person makes decisions and lives life. Hmong American adolescents live in two cultures with different values and need assistance in finding the strengths in both of these cultures. The Hmong core values are present in the lives of adolescents but may not be apparent in behaviors that represent adaptation to the American context (e.g., by not adhering to traditional courting methods). Parents think that their children have lost all values, and adolescents may feel isolated from their parents and the Hmong community as a whole; the adolescents may come to believe that their values are in opposition to traditional Hmong values. However, if we dig deeper at the meaning of the adolescents' activities and thoughts, we will see that some of these core Hmong values are very much in practice.

Based on the values assumption, the *Calm Heart: Ua Siab Tus Yees* program is structured to teach and stimulate discussions about Hmong history and values with a particular focus on how the pragmatic aspects of these values are apparent in the adolescents' everyday lives as Hmong Americans. The manual consists of 11 sessions; the first session is an introduction to the group, and the last session is dedicated to group termination and a celebration. One session focuses on Hmong history, five sessions are dedicated to each of the five core values (e.g., respect, ethics), and the remaining sessions are syntheses of two values (e.g., caring and hard-working in our lives) or an in-depth focus on a core value in everyday life (e.g., wisdom in our lives). The program defines the values in terms of how they might manifest in Hmong American adolescents and their experience living within a Hmong and American community. Within each session, group members have the opportunity to share any recent news or events in the community, home, or school, and to participate in structured exercises and open discussions related to the session topic.

Historically, Hmong culture was transmitted using oral and pictorial traditions. The Hmong would embroider family and historical events onto their clothing as a form of communication, called *pa ndau*. As a closing ritual, each session ends with group members making a modified version of *pa ndau* that reflects his or her reaction to or understanding of the value address within that session. As an opening ritual, group members will finish their *pa ndau* from the previous session. The closing and opening rituals serve as a bridge between sessions. At the end of the program, individual *pa ndau* squares from all group members are collected and sewn to make a quilt, creating a pictorial story. It is suggested that the quilt be donated to the setting where the group is initiated (e.g., school), further solidifying group members' experiences.

To date, the authors' have only anecdotal reactions and responses to the Hispanic and Hmong programs. Based on program evaluations, de la Luz and Coleman (2003) reported that the students enjoyed and were engaged in the program. A common response was that it was helpful to experience their culture of origin within the school to give their cultural being a sense of being valued. In both the African and Hispanic program, the groups were run by a member of the group's cultural group. In the Hmong program, teachers were trained to run the groups. We trained 16 counselors and teachers (all European American) to run the groups with Hmong adolescents. The groups were run in a school located in a rural area of a mid-Western state

where there has been a significant growth in the Hmong population. Although data concerning the adolescents was not collected in this round, the feedback from facilitators suggested an increase in awareness of culture and the roles that they can play in working with students from diverse cultures. The teachers reported that they enjoyed learning about Hmong culture and were emotionally moved by the stories their students' shared about their experiences of negotiating two cultures. This served to make the teachers more sensitive to the Hmong experience and more aware of the unique concerns of their Hmong students. The teachers also reported that parents contacted them concerning the group and were interested in attending a few of the sessions. The teachers also reported that the students enjoyed teaching the teachers about their culture and the opportunity to discuss the tension of living within two cultural frames of reference. These responses suggest that more systematic investigation of the process may yield useful information concerning ways to increase the multicultural competence of teachers.

Role in a School Counseling Program

The authors of this chapter consider group and classroom guidance a vital and central aspect of every school counseling program. We advocate that an important element of guidance in the middle school years should include an active discussion of the effect of cultural factors on an adolescent's sense of self. We believe that issues of class, gender, race, and other elements of culture should be a part of the regular conversation in schools. We believe, therefore, that an important aspect of classroom guidance should include these conversations. At the same time, there is a place for targeted conversations about these cultural factors among these adolescents, particularly influenced by factors such as gender or race. We advocate for the use of the type of programs presented in this chapter to be a central part of a middle school guidance curriculum. Whether these programs should be led by members of the cultural group reflected in the manual is an open question. We have utilized ethnic matching of leader and participant, for example, in the *Kwanzaa* program. In another program the *Calm Heart: Ua Siab Tus Yees* program, we have not used ethnic matching. Both approaches have been found to be valuable and effective. We do advocate, however, that pre- and postmeasures of academic performance and/or motivation be used in the evaluation of the groups.

Future work in the area should include empirical data to support the effectiveness of these interventions for their specific targeted groups; the use of comparison groups will further provide information on their effectiveness. Bass and Coleman (1997) found that the *Kwanzaa* program reinforced three assumptions: (1) cultural identity is an important factor in adolescent development, (2) middle school is a critical time to address these developmental issues, and (3) using a group to address these issues has developmental and practical value. Considering that ethnic/cultural identity development is not a static phase, future research should be extended to include postsecondary ethnic minority students and how they might benefit from such programs.

School counselors can play an important role in the proliferation of these types of programs. By introducing them into their counseling programs and evaluating their effectiveness, school counselors can develop models that other counselors in their district and state can emulate. As school counselors supervise the training of preservice school counselors, they can teach these models, which the school counselor in training can take to other schools. As to be expected, development, implementation, and evaluation of programs is a time-consuming activity. This activity, however, is a perfect way to collaborate or partner with university programs that train school counselors. The university partner is well situated to help with the development, evaluation, and dissemination of such a program, while the school counselor is well situated to implement and train staff to use such a program. We advocate for the school counselor to work with teachers to implement such programs as a way to enhance the multicultural competence of the teacher and his or her connections with the culturally diverse communities within the school.

Conclusion

We argue that middle school is an important time to help adolescents develop a positive image of cultural self and to become articulate about the challenges they face as members of their particular cultural groups. Cultural identity enhancement groups perform this very valuable function. This chapter has tried to convey that there is a way to help culturally diverse students enhance their sense of cultural identity. We believe that one's sense of self is deeply integrated into one's contextual relationships as articulated by Bronfenbrenner (1979). It is at this time, therefore, that systematic interventions need to be utilized to facilitate the development of one's sense of cultural self. The effectiveness of these programs suggests that at the minimum an equally important focus should be on how we see ourselves as members of a cultural group and what that means within the social contexts in which we live and work. By focusing more energy on formulating effective programs based on culturally relevant research, school counselors will be able to better address the issues related to the challenges culturally diverse adolescents are facing in achieving their

best academically and to foster psychological adjustment. The work of Bass and Coleman (1997) suggests that this can have a positive impact on the academic and social performance of culturally diverse adolescents. Furthermore, this chapter suggests that the more we engage teachers in the process, the more teachers will be committed to this important aspect of student development.

Implicit within this chapter is the belief that school counselors are the pupil services professionals within schools and have a primary responsibility for the positive emotional development of children. School counselors are best suited to facilitate the process of positive emotional development that will lead to academic accomplishment. In the middle school years, we can think of no developmental task that is more central than the acquisition of a positive and integrated identity. For culturally diverse students, this must include an articulate sense of cultural self in a pluralistic society. We believe that the programs presented in this chapter provide models for developing this positive sense of cultural identity and that this should be a focus of the school counselor's role within the middle school years.

Kwanzaa/Sphinx Program: A Program for Academic Motivation Enhancement in African American Male Middle School Students

Christopher K. Bass, MS and Hardin L. K. Coleman, PhD

University of Wisconsin–Madison

Session 1 Overview

Concept: Umoja (Unity)

The principle Umoja will be presented to the boys and discussed. The key concept is the placing of high value upon relationships. The activity will involve having each boy self-disclose personal information about himself. This is a powerful exercise because it enables the boys to learn more about the other members of the group.

Session Objectives

- By the process of bonding/joining, participants will be able to let their defenses down and participate.
- Each participant will learn why he is in the group.
- Participants will learn about the rules and benefits of group membership.

Session Format

1. Opening exercise
2. African/African American history
3. Discussion on Kwanzaa Symbols
4. Member responsibilities
5. Group discussion of week activities ("Open Forum")
6. Introduction of concept
   a. What does this mean to you?
   b. Group discussion
7. Closure of session

Lesson 1 Plan

Opening Exercise (approximate time: 15 minutes)

Introduction Exercise

Introduce yourself to the group members. Ask each person to talk briefly about where he is from, how he came to be in the group, what he hopes to accomplish in the group, and what are his dreams.

Ground Rules

Briefly outline the following group parameters. These should be shared in a positive manner as the parameters are meant to facilitate group cooperation and cohesiveness. Group members are also encouraged to add to this list of ground rules.

- What goes on in group, stays in group.
- Attendance at each session is very important. Ask members to plan to attend all sessions.
- Knowledge of the motto and pledge of the group is important.
- Support of others is welcome. Constructive criticism used to facilitate work is acceptable. However, negative criticism and rudeness are not accepted and are discouraged.
- Each member is responsible for his own behavior.
- Members are responsible for the wearing and keeping of group symbols.

At the end of the discussion concerning ground rules, give members a chance to ask questions.

African/African American History (approximate time: 15 minutes)

This section is created to expose the African American young men to African world views and to enhance self-esteem/self-perception by including African/African American history in the formal learning environment. Facilitators of this group must be knowledgeable of some African/African American history. Information for different subjects may be gained through reading any African/African American history literature.

Open Forum (approximate time: 20 minutes)

This section of the program is created to give the participants an opportunity to discuss what has happened in their week. Whether they have good

information to share or bad information to share, this section is designed for students to speak on what events have occurred during the week. Many times, participants may speak on events occurring at home (encourage this) or at school. Remember this is their time to speak. This is their space. Try to limit discussion time to 15 minutes. However, if a subject is too intense to disrupt, allow ample time for wrap up (use your own judgment).

Introduction of Concept
(approximate time: 15 minutes)

The Kwanzaa group, which is Afrocentric in nature, will incorporate into it the concepts of Kwanzaa. This part of the Kwanzaa group is powerful in the fact that it not only teaches the young men important aspects of their culture but links them to positive qualities of a past history that they might not have gotten an opportunity to experience. Giving the boys a past history (besides slavery) gives them something to draw upon when confronted by the ugliness of racism in this society.

The principles are based on *Kawaida Theory* (Karenga, 1980). The principles are used to expose and connect the boys to positive images in the African American culture. The seven principles are (1) *Umoja* (unity), (2) *Kujichagulia* (self-determination), (3) *Ujima* (collective work and responsibility), (4) *Ujamma* (cooperative economics), (5) *Nia* (purpose), (6) *Kuumba* (creativity), and (7) *Imani* (faith).

Principle one, which is Umoja, should be discussed in the first session. Participants should know how to pronounce the word and tell what it means to them. Each student should speak on unity. A group discussion on unity should ensue after each has described the concept in his own words.

Materials Needed

- Copy of the Kwanzaa Group Pledge
- Copy of the Kwanzaa Group Shield
- Afrocentric symbols (Ankh) for each member

Lecture Format

The following sample lecture is provided for you. Its content covers the major points just outlined. You may use the lecture verbatim or you can use your own words to convey the information. If you choose to use your own words, be careful to cover the major content and themes that are contained in the sample lecture.

Sample Lecture

Greetings, my name is ..... Congratulations on being accepted into the Kwanzaa Group. I am the leader of the group but this group belongs to you. This is **your** group. Can anyone tell me what he thinks this group is all about? In a minute I would like for us to go around and tell who we are, why we are here in the group, and what you hope to learn from the group. You already know my name, but a little background information on me is ..... This group is called the Kwanzaa Group. It will meet for 16 sessions. In these sessions we will discuss a lot of different things. We will talk about school, home, and how we feel. I want to start this session off by explaining the pledge of the group. The pledge goes, ***"Through knowledge perseverance and self-respect, I shall uplift myself and my race."*** Each of you will receive a copy of the pledge. All of you should know it by the next session. We say this pledge at the beginning and end of each meeting. Also, in time you will be expected to learn about the shield of the group. Like all groups, we have a shield that represents us. In the shield there are many different symbols and hidden meanings. The main symbol on the shield is the Sphinx. The Sphinx is a mystical figure originating in the African country of Egypt. Although we will discuss the origins of the Sphinx and many other symbols, for the shield, the Sphinx means pharaohs (who were Egyptian kings). The next symbol is the torch, on the shield the torch means knowledge. The next symbol is the Ankh; this symbol looks like a cross with a hole in the top; this means life. The next symbol is the pyramid, which means strength. As with all great clubs, all of these symbols are secret. Do not discuss these outside of the group.

Each of you will receive an Ankh to wear. These Ankhs are very special. You are responsible for them. Each member must wear his Ankh to each meeting. This is one of the ground rules. Other rules include (refer to rules section). Each week we will talk about things that are happening with you; whether it's school related or home related. It's up to you, we can talk about whatever you need to talk about.

Each week we will talk about a lot of different things. Can anyone tell me the name of this group? [The Kwanzaa group is the name]. Does

anyone know about Kwanzaa? Can anybody tell me a Kwanzaa principle? This week we will talk about *Umoja*, which is Kiswahilii for unity. Let's talk about what it means to have unity. **Have each student discuss unity.** [It is important to talk to the young men in terms they can understand. Make it fun for them]. By this time, the hour should almost be completed, and participants should be encouraged to ask questions. It is important to also discuss with them the different types of paper work for which they will be responsible. The paperwork includes *Weekly behavior charts* (to be given to their teacher and returned to you at the end of each week) and *Academic goal planner/and chart miscellaneous homework projects.*

Closure of Session (approximate time: 5 minutes)

1. Summary of major points covered in session
2. Reminder of next scheduled meeting
3. Questions
4. The pledge
5. Goodbye

Session 2 Overview

Concept: Kujichagulia (Self-Determination)

This session will be presented in the form of a walk back through history. We will dissect some of the terms of African American culture and challenge the boys to enlighten their minds by asking questions relating to topics such as ancient African civilizations, kings, slavery, crime, and drugs in the community. Because of the lack of culturally relevant topics presented to the boys in the public school system, we believe that this exercise is more of an educational tool that will help the boys understand what they were and what they are as a people. The first phase of the rites of passage will be completed.

Session Objectives

- To explore myths and falsehoods about the African American culture
- To give participants an opportunity to discuss issues regarding their neighborhoods
- To expose participants to African history
- To complete the first phase of the rites of passage experience

Session Format

1. Opening exercise
2. Review of Session 1
3. African/African American History (Ceremony 1: Presenting of Ankhs)
4. Open forum
5. Introduction of new concept
   a. What does it mean to you?
   b. Group discussion
6. Closing exercise
7. Session closure

Lesson 2 Plan

Opening Exercise (approximate time: 7 minutes)

1. Kwanzaa pledge
2. Go over the symbols of the Kwanzaa shield and their meanings.
3. Collect teacher response sheets.

Review of Session 1 (approximate time: 15 minutes)

1. Go over group rules.
2. Briefly revisit past concept (Umoja).

African/African American History (approximate time: 20 minutes)

This week you should talk about Africa. Mention facts such as Africa is the second-largest continent in the world with an area of 12 million square miles. Find a current map of Africa and explain how most maps show the United States and Africa as equal in size, but Africa is almost 3 times as large. Understand that the only information about Africa that these children have is what has been presented to them by the media and the current educational system. These two realms of education often depict Africa in a negative light. It is up to you to add new insight to this great land. More information that you should mention includes Africa is not one country, but 54 different countries; the longest river in the world, the Nile, is located there (the Nile will be explored further in the Sphinx Club). Talk about the great empires and statues of Egypt, specifically the reigns of Ramses, Akenaten, and Tutankhamen, the Pyramids (Giza) and, the Sphinx (mention Chephren). After the history session, participants should be lined up according to height (shortest to tallest) and presented with their first Ankhs.

Diop, C.A. (1974). *The African origin of civilization*. New York: Lawrence Hill.

Kunjufu, J. (1987). Lessons from history: A celebration in Blackness Jr.–Sr. high edition. *African American Images*, Chicago, IL, 1–11.

Open Forum (approximate time: 15 minutes)

This section of the program is created to give the participants an opportunity to discuss what has happened in their week. Whether they have good information to share or bad information to share, this section is designed for students to speak on what events have occurred during the week. Many times participants may speak on events occurring at home (encourage this) or at school. Remember that this is their time to speak. This is their space. Try to limit discussion time to 15 minutes. However, if a subject is too intense to disrupt, allow ample time for wrap up. (Use your own judgment.)

Introduction of Concept
(approximate time: 15 minutes)

The new concept this week is Kujichagulia, which means self-determination. Participants should be taught how to spell and pronounce the word and should tell what it means to them. Each student should speak on self-determination. A group discussion on self-determination should ensue after each has described it in his own words.

Materials Needed

- Copy of the Kwanzaa Group Pledge
- Copy of the Kwanzaa Group Shield
- Afrocentric Symbols (ANKH) for each member
- Map of Africa
- World map

Lecture

Closure of Session (approximate time: 5 minutes)

1. Summary of major points covered in session
2. Reminder of next scheduled meeting
3. Questions
4. The pledge
5. Goodbye

Session 3 Overview

Concept: Ujima *(Collective Work and Responsibility)*

The principle of Ujima will be presented to the boys in the form of an activity that will involve going to a neighborhood grocery store and picking out the groceries needed to create a meal. Each participant will be responsible for making one dish. After all dishes are completed, each will present the dish to the group. This activity was chosen for many reasons: (1) the boys will depend on each other for help in preparing their dish; (2) they will have the responsibility of creating a piece of the meal; and (3) the skills for grocery shopping and preparation of food are skills that young men should experience and have knowledge of (having the capabilities to take care of oneself).

Session Objectives

- To expose participants to the concept of *Ujima*
- To allow participants to be responsible for preparing a part of a collective project
- To give participants a life skill (grocery shopping and food preparation)
- To further the bonding process among participants

Session Format

1. Opening exercise
2. Review of Session 2
3. African/African American history
4. Open forum
5. Introduction of new concept
   a. What does it mean to you?
   b. Group discussion
6. Closing exercise
7. Session closure

Lesson 3 Plan

Opening Exercise (approximate time: 5 minutes)

1. Kwanzaa Pledge
2. Have participants go over the symbols of the Kwanzaa shield and their meanings.
3. Collect teacher response sheets.

Review of Session 2

1. Ask questions such as, What is the longest river in the world? What is a pyramid? Who was King Tut?

2. Briefly revisit past concept (*Kujichagulia*).

African/African American History

Because grocery shopping and cooking times may get extensive, this week's discussion should be centered on the topics discussed last week (i.e., the pyramids, pharaohs, Egypt, etc.). The discussion may take place in the car, grocery store, or even during cooking.

Open Forum

This entire session is basically an open forum. However, if participants want to speak about events in their community, home, or school, specifically encourage this.

Introduction of Concept

The new concept this week is Ujima, which means collective work and responsibility. Participants should be taught how to spell and pronounce the word and should tell what it means to them. Each student should speak on collective work and responsibility. A group discussion on collective work and responsibility should ensue after each has described the concept in his own words. Point out that this week's events have been an example of *Ujima*.

Materials Needed

- Copy of the Kwanzaa Group Shield
- Transportation to and from grocery store
- Approximately $25 for groceries
- A cooking facility

Lecture

Closure of Session

1. Clean up
2. Reminder of next scheduled meeting
3. Questions
4. The pledge
5. Goodbye

Appendix B

Please note: The first three sessions are included. The complete manual can be found at http://www.education.wisc.edu/cp/faculty/hcoleman/

Ua Siab Tus Yees: Calm Heart Manual

A Yang, MS
University of Minnesota–Twin Cities

Sara Cho Kim, MS Ed
and Hardin Coleman, PhD
University of Wisconsin–Madison

Session 1 Overview

Introduction

Session Format

1. Opening introductions
2. Cultural identity exercise
3. Introduction of Hmong values
4. Closure of session

Materials Needed

- Cloth squares
- Fine point permanent markers (variety of colors)
- Copies of the cultural values exercise

Session 1 Introduction

Opening Introductions

1. Member introduction
2. Facilitator introduction
   - My name is _____. Congratulations on being accepted into the Calm Heart: Ua Siab Tus Yees group. We are the leaders of the group but this group belongs to you. This is your group.
3. Ask members what their purpose is in joining the group and what they hope to learn from the group.
4. Inform members of the general purpose and structure of group:
   - I want to tell you about the Calm Heart: Ua Siab Tus Yees group. It will meet 11 times. We will start each session with a ritual and end with a ritual. Each one of you will have the chance to do many individual drawings, similar to a *pa ndau*.[1] We will work on this in the beginning and end of each session. At the end of our time together, the individual drawings will be sewn together into a quilt and perhaps we can donate it to the school. In the group we will discuss a lot of different things. We will talk about school, home, what we think, how we feel, and being Hmong American.
5. Discussion of what it means to be a member of a group:
   - Developing ground rules (from the group or by facilitator), for example, confidentiality, attendance, support of other, negative criticism and rudeness are not accepted. "These rules will be announced each week by a different member to remind us of where we are and what other members would like and need from us."

Cultural Identity Exercise

My two worlds exercise from *Who Am I?*[2] can lead to discussion of cultural identity and biculturalism.

Start the group on the *pa ndau*, or cloth drawing,[3] for example, a drawing of things they like in Hmong culture and American culture.

Introduction of Hmong Values

1. Introduce concept of Calm Heart: Ua Siab Tus Yees:[4]
   - What does Calm Heart: Ua Siab Tus Yees mean?
   - Open discussion and interpretation.
2. Hmong values
   - What are some values that your parents have?
   - Introduce Core Values as focus of sessions.[5]

---

[1] *Pa ndau* are stitched needlework that was originally used to adorn Hmong clothing and also became used as a way to record Hmong history and culture. The embroidery on the *pa ndau* tells a story that depicts aspects of the Hmong experience (e.g., war and death; village life).

[2] *Who Am I?* is an activity book designed to help Latina girls develop positive self-esteem (efforts of the U.S. Department of Health and Human Services). For more information see www.soyunica.gov. The activity worksheet has been adapted for the purposes of this manual.

[3] Each group member will complete one square cloth drawing reflecting how each of the five values may manifest in their lives today as a Hmong-American youth (for a total of five squares per group member). Fine point permanent markers should be used. The individual squares will be sewn together to create a quilt. It is suggested that the quilt be donated to the setting where the group is initiated (e.g., school).

[4] *Calm Heart: Ua Siab Tus Yees* is an ideal principle that encompasses the core Hmong values which guide how to live life as a good Hmong person. For more detail, see the introduction to the manual.

[5] See introduction to the manual for description of the five core values.

Closure of Session

1. Summary of major points covered in session
2. Reminder of next scheduled meeting
3. Questions

My Values

It is very important to know your values. What are values? They are guides to show you how to live and act. Therefore, they have great meaning in your life; they show that you are part of your family and culture.

These are basic elements for your identification as a person and to learn about your cultural heritage. That way, you will feel proud of it.

These values are a part of your identity, and they influence the decisions you make and your conduct, habits, ideals, rules, and goals.

You live in a Hmong culture and a North American culture. It is also important to your identity to know what aspects of each culture that you like.

My Two Worlds

Aspects of Hmong culture that I like: (Example: the food)	Aspects of American culture that I like: (Example: the music)

Session 2 Overview Hmong History

Session Format

1. Have member read ground rules.
2. Opening ritual
3. Open forum
4. Purpose
5. Hmong history
6. Exercise
7. Open discussion
8. Closure of session
9. Closing ritual

Materials Needed

- Cloth squares
- Fine point permanent markers (variety of colors)
- Paper, pens, and pencils
- Maps of Southeast Asia

Session 2 Hmong History

Ground Rules

Have a group member read the list of group rules generated in Session 1.

Opening Ritual

Cloth drawing (Finish picture from last session.)

Open Forum

To share any recent news or events in the community, home, or school. (Facilitators should use their best judgment on sensitive or negative topics.)

Purpose

To provide the group with a background of Hmong history. This will give group members a base from which the Hmong values stem. Participants will have the opportunity to compare and contrast Hmong history with the present conditions of Hmong life.

Hmong History

The main focuses of Hmong history:[6] (1) origins, (2) life in Laos, (3) role and outcome in the Vietnam War, (4) political asylum/immigration, and (5) life in the United States.

Exercise and Open Discussion

Have members write what they know about Hmong history related to the five main points just listed. Ask for two volunteers to share what they have written. This will be an open discussion; other members are welcome to expand or add anything else that they know. Facilitators should be prepared with information to fill in what members have not brought up.

Break main group into five smaller groups; each group will be assigned one of the five main foci of Hmong history and collaboratively write

[6] For more information, facilitators should read about Hmong history, for example, Fadiman, A. (1997). *The spirit catches you and you fall down.* New York: Noonday Press.

what was just discussed and information that was given. The written material will be put together into a book and each member will receive a copy along with a map of Southeast Asia.

Closure of Session

1. Summary of major points covered in session
2. Reminder of next scheduled meeting
3. Questions

Closing Ritual

Cloth drawing (Draw new one on history.)

Session 3 Overview Hard Working

Session Format

1. Have member read ground rules
2. Opening ritual
3. Open forum
4. Purpose
5. Introduce value of hard work
6. Exercise
7. Open discussion
8. Closure of session
9. Closing ritual

Materials Needed

- Cloth squares
- Fine point permanent markers (various colors)
- Copies of the folk story

Session 3 Hard Working

Ground Rules

Have a group member read the list of group rules generated in Session 1.

Opening Ritual

Cloth drawing (Finish picture from last session.)

Open Forum

To share any recent news or events in the community, home, or school. (Facilitators should use their best judgment on sensitive or negative topics.)

Purpose

To provide a group experience that will allow participants to gain insight into the value of hard work in traditional Hmong culture. To revisit the history of Hmong people, particularly related to the value of hard work. To give participants the opportunity to compare and contrast their personal view of hard work with that of their elders.

Value: Hard work

Saving for the future, laborious work, thrift, do well in school, housework (cook, clean), not complaining, not sitting around and doing nothing but instead being productive, and delayed gratification of work.

Exercise

Read a folk story that reflects the meaning of hard work just described. The group may alternate reading each sentence or paragraph if agreed upon.

Folk Story: Raising Rice[7]

Before we plant the rice, we must clear the fields. We use an ax or knife to cut the trees. We use a shovel to clear the land and make it smooth. We let the trees dry in the sun for several months. Then we burn the trees that we have cut. After we plant the rice seeds, we check on the rice every day. There is an insect called the *kooj*, or grasshopper, that eats the rice. We have to catch the grasshopper. We catch the grasshoppers at night with a light and put them in a bamboo basket with a top. We also spray the fields. When the rice is tall, the birds eat it, so the men use a *hneev*, or crossbow, to kill the birds that eat the rice. When the top of the rice plant curves down, the rice is ready to cut. We cut the tops off the plants. The men and women shake a flat bamboo basket. The leaves fall on the ground, and the rice stays on the flat basket. The rice is stored in a big bamboo storage bin. When the family needs rice to cook for food, it gets rice from the bamboo bin. The women put the rice seeds into a big round wooden barrel. The barrel has a long pole on one side. The women step on one end and make it move like a hammer. The hammer hits the rice seed and knocks the rice off the shell, and then it is ready to cook.

Open Discussion

- In Laos: What sort of work did Hmong families (for example, each family member) have to do?

[7] Folk story was taken from Cha, D. & Livo, N.J. (2000). *Teaching with folk stories of the Hmong: An activity book*. Westport, CT: Libraries Unlimited.

- In the United States: What sort of work do Hmong families do in the United States? What are the similarities and differences?
- How do you think these changes are affecting the Hmong parents, children, grandparents, and so on?
- What does hard work mean to you? How are you a hard worker? What does hard work look like?

Closure of Session

1. Summary of major points covered in session
2. Reminder of next scheduled meeting
3. Questions

Closing Ritual

Cloth drawing (Draw new one on hard work.)

Appendix C

Please note: The first three sessions are included. The complete manual can be found at http://www.education.wisc.edu/cp/faculty/hcoleman/

Fortaleciendo Nuestras Raíces (FNR): Strengthening Our Roots Manual

Maria de la Luz Perez de Olmos, MS and Hardin Coleman, PhD

University of Wisconsin–Madison, Department of Counseling Psychology

FIRST STAGE

Session 1

Value: Personalismo

Objectives

Students will know the rules and goals in general of this group and will learn the first value, Personalismo.

Getting Started

Optional: Before the group starts, take a picture of everybody and put the pictures with their names on a poster with a cornstalk drawing, so everybody will see it during each session. The corn plant will be a central element in our group process. You also can have Latin music while waiting for everybody to get ready to start. (You can ask the students to bring Latin music that they like to listen to before starting the session.)

You can write the proverb in a corner of the board before the group starts. Do it every time in the same place so the participants become familiar with it.

Dicho/Proverb: "No dejes para mañana lo que puedas hacer hoy." Don't leave for tomorrow what you can do today.

Activities (approximate time: 35 minutes)

1. (5 minutes) Introduce yourself to the group members. Congratulate them for being part of the Fortaleciendo Nuestras Raíces group. Tell them that the group belongs to them. Ask what they think this group is about. Ask each person to talk briefly about where he or she is from, what he or she likes to do in his free time, and what he or she hopes to accomplish in the group. Tell them a little bit about your background and your expectations in general.

2. (5 minutes) Tell participants about the ground rules and ask them if there are more rules they would like to include.

Ground Rules

- **Respect.** Constructive criticism is acceptable, but negative criticism or rudeness is not.
- **Responsibility.** Attendance at each session is very important. Each member is responsible for his or her own behavior.
- **Confidentiality.** What goes on in group, stays in group.
- **Membership.** Members are responsible for wearing and keeping of group symbols.

3. (5 minutes) Latino culture and history. You can start by asking where students come from, where their families come from, what countries Latinos come from, and where most of the Latinos are in the United States. Ask if they have relatives in the United States and where they live. You can bring a map to facilitate the discussion. You can give a brief narration of the Latino history in the United States. Tell participants briefly about the Latino history since the Spaniards colonized the Latin American countries. Tell them about the race mixture that is among Latinos (Spaniards, Indians, and African descendents). Ask if they know about their own race background. You can get Latino history in the books or any other resource accessible to you.

4. (10 minutes) Introduce the idea of the corn plant. Tell students about the importance of corn among Latinos. Ask who eats tortillas or other corn products. Tell them how the corn was first harvested by the Aztecs. Make the analogy of this group and the corn plant: At the end of the group we are going to harvest corn (goals), but first we need to strengthen the roots of this corn plant and then get ready to produce our fruit, the corn.

Tell them what every part of the corn stalk means in relation to the process of the group. "We are going to develop our corn plant. First, we will have to strengthen the roots of it, so our plant can be

strong and can absorb the soil nutrients. The roots of our plant will be our values. Our values as Latinos are Personlismo, Respeto, Simpatía, Dignidad, Confianza, Familismo, and Fe/Espiritualidad. Once we learn and strengthen our values (root), we are going to develop our corn stalk. This means that we will learn more about ourselves. Later we will develop the leaves, which means that we are going to get ready to put forth the product, the corn. In this part we are going to learn skills that will help us to be able to produce. Finally, we are going to produce our last product, the corn (changes and actions)."

Symbols

El maiz
Raices (Roots) = Latino values
Caña (Stalk) = knowing my self
Hojas (Leaves) = learning, getting ready to produce
Maiz (Corn) = service, change, action

5. (5 minutes) Necklace Initiation Ceremony

Explain that the first 8 weeks will be dedicated to strengthening our values. Therefore, participants will be using a necklace with an image of roots. Then in the second part we will develop everything else in our corn plant (stalk and leaves) to leave it ready to harvest. In this part, participants will be using another necklace with an image of corn stalk on it that will represent what they are getting ready to produce.

The participants will receive their first symbol for the first 8 weeks. When the students receive the necklace, they say the pledge aloud. Once everybody has his necklace, all say the pledge again. Tell students that the pledge will be used always at the beginning and end of each session. You can ask the students what the pledge means.

Pledge

Através de nuestras raíces culturales fortaleceremos nuestro ser y nuestro espíritu. (Through our cultural roots we strengthen our self and spirit.)

For the first session you can make copies of the pledge for each one. Participants should memorize it for the next sessions.

6. (5 minutes) Introduce the first value: Personalismo. *Personalismo* is a very important value for Latinos. It emphasizes personal interactions. For us, Latinos, our relationships are very important. For example, our relationships with our family, friends, neighbors, and classmates are very important. For us, the interdependency and cooperation are important as part of Personalismo. Who can tell me what you know about interdependency? Interdependency is the belief that we are social beings, and we depend on others as others depend on us. For example, the teachers need us and we need them as well. Another example is a soccer team. Everybody needs everybody else to win. What does cooperation mean? Why do you think this is important for Latinos to be cooperative?

Group Discussion (approximate time: 10 minutes)

During this time, participants can talk about their experiences during the week. They can share good or bad news. Students can talk about what happens at school or at home. Emphasize that this is a time to speak. Be aware of the time and be sure to wrap up the conversation before moving to the closure.

Closure (approximate time: 5 minutes)

- Summary of major points covered in session
- Reminder of next scheduled meeting. Ask the participant to think of a person that they *respect* in their family and in their communities and think about why
- Questions
- The pledge

Material

- Latin music
- Boom box
- Big corn drawing
- Camera
- Corn drawing on which to put students' pictures
- Stickers on which to put names
- Symbols
- Copies of the FNR pledge
- Necklaces for first period

Session 2

Value: Respeto (Respect)

Objectives

Students will learn and talk about respect. Students will learn about Latino history.

Dicho: "El respeto al derecho ajeno es la paz" (Peace will come if we respect what is not ours.) Being honest is a very important virtue.

Latin Music

Activities (approximate time: 35 minutes)

1. (2 minutes) In group, say the FNR pledge.

2. (3 minutes) Review last session. Remember the ground rules. Revisit the last value (Personalismo).

3. (10 minutes) The value that we will talk about today is Respecto. *Respect* has two elements. One is the attitude of not being rude or damaging oneself or others. The other is related to the admiration of authority figures.

You can ask the students these questions to enrich the discussion:

- Who are authority figures for you?
- What do you do to respect them?
- What do people do when they do not respect others?
- What do you do when others do not respect you?

4. (10 minutes) Individual activity. Ask the students to do the exercise in Appendix 2. Explain that they have to write what they have done to respect themselves and what they have done to not respect themselves. Then ask them to write what they have done to respect others and what they have done to not respect others. Finally, they have to write what they could do differently to respect themselves and others. Once everybody has finished, ask volunteers to share some of their responses.

5. (10 minutes) Latino history. "Respect has existed since the ancient cultures in America. Old people were considered wise. They had a high status in society."

Ask students the following question to enrich the discussion:

- What cultures have you heard about? (Mayas, Aztecs, Incas, etc.) If you can, bring pictures of the Indians who inhabited Latino America.
- What do you know about those cultures?
- Where do Latinos come from?
- What are Latino America countries?
- Where are they located on a map?
- What traditions do those countries have?
- What do you know about these countries?

Group Discussion (approximate time: 10 minutes)

During this time, participants can talk about their experiences during the week. They can share good or bad news. Students can talk about what happened at school or at home. Emphasize that this is a time to speak. Be aware of the time and be sure to wrap up the conversation before moving to the closure.

Closure (approximate time: 5 minutes)

- Summary of major points covered in session
- Reminder of next scheduled meeting
- Questions
- The FNR pledge

Material

- Boom box
- Latin music
- Copies of *respecto* activity
- Copies of pledge

Session 3

Value: Simpatia

Objective

Students will learn more about the Latino history and about the Simpatia value.

Dicho: "Aquellos son ricos, que tienen amigos." (Those who have friends are rich.)

Activities (approximate time: 35 minutes)

1. (2 minutes) In group say the FNR pledge.

2. (3 minutes) Briefly review last session value, *Respecto*.

3. (10 minutes) Explain today's value. "The value to talk about today is *Simpatia*. Latinos like to be perceived as likeable, attractive, fun to be with, and easygoing. In general this emphasizes the promotion and maintenance of harmony with people around us, such as friends, family, neighbors, and classmates."

4. (20 minutes) Tell students that they will do a collage about what friendship and harmony mean to them. Invite them to think about their friends, why they are their friends, and what they like about their friendship. Later you will ask the students to share their collage with everyone else and talk about what friendship means to them.

Alternative Activity: Instead of doing the collage, you can ask the students to select a rock, which they will paint and give to a member in the group as a symbol of friendship. When they give the rock to somebody else, they have to say what friendship means to them and what they like about this person. To be sure that all students receive a rock from somebody else, you can do a lottery with participants' names so everybody will pick a different group member.

Group Discussion (approximate time: 10 minutes)

During this time, participants can talk about their experiences during the week. They can share good or bad news. Students can talk about what happened at school or at home. Emphasize that this is a time to speak. Be aware of the time and be sure to wrap up the conversation before moving to the closure. Ask the students to share experiences with friends.

Closure (approximate time: 5 minutes)

- Summary of major points covered in session
- Reminder of next scheduled meeting
- Questions
- The pledge

Material

- Boom box
- Latin music
- Video
- Magazines with Latino people and others
- Papers
- Scissors
- Glue

If you do the friendship rocks activity, you will need the following:

- Rocks
- Paint and brushes
- Water
- Towel
- Bowl of water
- A basket

6

Working with Socio-Emotional Challenges

XXXVI
INTERPERSONAL RELATIONSHIPS

STEPHANIE T. PITUC
University of San Francisco
TRACY R. JULIAO
Genesys Regional Medical Center, Grand Blanc, Michigan

Students' experiences in school are hardly limited to individualized academic endeavors. Academic achievement and personal development occur within the context of a number of interpersonal relationships among peers. Interactions with classmates, friends, foes, cliques, and romantic interests color the everyday experience for students, and the literature on childhood and adolescence recognizes the important role that peer interaction plays in the socialization process and academic adjustment (Parker & Asher, 1987). School counselors play a critical role in facilitating students' positive interpersonal relations and managing the challenges involved at the dyadic, group, and schoolwide level. Possessing the requisite knowledge and skills to attend to facilitating positive peer relations, school counselors can bridge the gap between students' needs with respect to academic success and positive psychosocial functioning.

Currently, a number of academic fields (e.g., School Counseling/Counseling Psychology, Educational Psychology, School Psychology) examine various interpersonal issues in isolation or address personal/social development at the individual level (see Bodenhorn, chapter 15, this volume). This chapter synthesizes the research and theory on the major socioemotional issues in student interpersonal relationship development within a peer-centered, relational framework. We also acknowledge the complex factors and forces which impact these connections, taking into account not only individual characteristics but also more systemic influences such as school and community contexts. We provide a general review of the literature in these areas as a backdrop for thinking about how school counselors can facilitate positive interpersonal relationships through individual, group, and systemic interventions. The first half of the chapter will provide an overview of theory and research in the areas of (a) friendship; (b) social networks; (c) rejection, withdrawal, and isolation; and (d) romantic relationships. The second half of the chapter will discuss school counseling intervention strategies emphasizing the facilitation and promotion of positive interpersonal relationships. We provide a general review of the literature in these areas as a backdrop for thinking about how school counselors can facilitate positive interpersonal relationships through individual, group, and systemic interventions.

Friendship

Once children begin school, their social world expands beyond the family, and their roles shift from child to student/peer. As students spend a greater proportion of time with their peers, peer relations become increasingly important and mere propinquity fosters the formation of close friendships. These relationships are usually unlike more involuntary relationships formed prior to coming to school, such as those associated with family. Bukowski, Newcomb, and Hartup (1996) described friendships as a unique kind of interpersonal relationship with respect to three conditions: (a) *reciprocities* (i.e., benefits that come about from mutual social exchange), (b) *liking* (i.e., preferring to spend time with one over others), and (c) *emotions* (e.g., affection and having fun).

Functions Served by Friendship

Developmental needs alter the way the conditions of friendship are sought and fulfilled (Brown, 1989; Gifford-Smith & Brownell, 2003). During the early school years, friendships are formed primarily around play and small classroom activities. In middle childhood, the child begins to seek acceptance from peers (Brown & Klute, 2003). In preadolescence and adolescence, there is an emerging need for intimacy and a desire for friends who are sensitive to one's needs and

can supply mutual satisfaction (Berndt, 2002; Sullivan, 1953). Friendships also act as social support and facilitate school adjustment in the transitions between grades and schools (Berndt & Keefe, 1995; Ladd & Kochenderfer, 1996; Wentzel, Barry, & Caldwell, 2004).

During the middle and high school years, close interpersonal relationships may facilitate the critical task of identity formation (Erikson, 1968). The friendship patterns along race and ethnicity suggest that this may be an especially critical period for racial and ethnic identity development. Racial/ethnic minority students tend to choose culturally similar friends (Way & Chen, 2000) despite differences in academic orientations and deviant behaviors and attitudes (Hamm, 2000; Tolson & Urberg, 1993). For example, African American students, more than Asian American and European American students, showed less similarity than their friends in terms of academic variables such as GPA and goals but were more similar on ethnic identity and substance use (Hamm). Racial/ethnic minority adolescents who demonstrate strong in-group preferences also choose racially/ethnically similar friends (Hamm, Brown, & Heck, 2005), which may be a function of the relative importance of social group membership to their self-definition above other factors (Fordham & Ogbu, 1986). Grounded in these similarities, friendships provide the context for exploring a range of attitudes and behaviors (Hamm).

Types of Friendships and Associated Outcomes

Research regarding childhood friendship has unequivocally reported that having friends is associated with more positive outcomes than not having friends (Bukowski et al., 1996). Having friends has been correlated with positive outcomes for self-esteem, adjustment to school, family relationships, preventing delinquency, buffering of relational aggression from other peers, promotion of prosocial skills, cognitive development, and the development of morality (Bagwell, Newcomb, & Bukowski, 1998; Berndt & Keefe, 1995; Bukowski & Sippola, 1996; Hartup, 1996; Hodges, Boivin, Vitaro, & Bukowski, 1999). Benefits such as successful social coping and greater psychological well-being extend into adulthood and old age as well (Hartup & Stevens, 1997).

In response to criticism regarding assumptions found in the literature that all friendships are the same (Bukowski et al., 1996), recent research on friendship has extended beyond a focus of merely having friends to characteristics of friendships and their possible consequences (Hartup & Stevens, 1997). There has been a recent push to distinguish between types of friendships, such as close and general friendships (Harter, 1990; Way, 1996), and positive and negative qualities of friendships. For example, exploratory research on the close and general friendships of racial/ethnic minority adolescents from low-income families showed that the correlates of friendship quality (e.g., family support, school climate, and psychological well-being) differed across friendship type (Way & Chen, 2000).

Friendships can also be supportive and mutually satisfying or imbalanced and conflict-ridden though they often encompass both positive and negative traits. Research has found that both characteristics in friendships impact multiple areas of an individual's adjustment and well-being. For example, Berndt and Keefe (1995) found that students who reported more negative friendship characteristics (i.e., conflicts and rivalry) demonstrated greater disruptive behavior. This outcome was magnified when the friendship was also seen as highly supportive, thus reinforcing negative social interaction styles with other peers and teachers. Higher quality friendships (as measured by companionship, affection, disclosure, nurturance, instrumental aid, approval, support, reliable alliance, and satisfaction; Furman & Buhrmester, 1985) also appeared to protect against social anxiety. On the other hand, adolescents with lower quality best friendships (as measured by reported conflict, criticism, exclusion, dominance, and pressure; Furman & Buhrmester) reported more symptoms of social anxiety and depression (La Greca & Harrison, 2005). In one of the few studies on cross-race friendships, Aboud, Mendelson, and Purdy (2003) found that having a high-quality friend of a different race was associated with attitudes of less racial bias.

While some researchers posit that high-quality friendships increase self-esteem, a review of work in this area reveals inconsistent findings (Berndt, 2002). A limitation for much of the research regarding friendship outcomes is that studies are primarily correlational in nature, and thus do not provide insight into the processes mediated by high- or low-quality friendships. Further, the direction of the relationship between the correlated variables is unclear (Berndt; Bukowski & Sippola, 1996; Hartup, 1999).

Conflict in Friendships

In the research on the interpersonal dynamics of friendship, conflict often serves as a marker for low-quality friendships, in addition to other negative behaviors and attitudes such as dominance, criticism, exclusion, and pressure (e.g., Furman & Buhrmester, 1985). Yet friends experience conflict through fighting and arguing just as much as nonfriends do (Berndt & Perry, 1986). As children become older, they come to understand that the mere presence of conflict or disagreement does not threaten relationships but that the quality of the friendship is a function of how conflicts are handled (Laursen, 1996). Ways of coping with interpersonal

conflict vary widely, perhaps as a function of gender and cultural socialization. For example, some research suggests that females are more sensitive to the costs of conflict and tend to emphasize compromise and negotiation (Collins & Laursen, 1992); concomitantly, females tend to negotiate conflict by withdrawing less and utilizing higher communication skills and support-validation (Black, 2000).

Variables such as cultural values, immigration status, and acculturation may particularly play a role in interactions for culturally diverse youth. Language barriers, the school climate, and school practices such as tracking may obscure opportunities for cross-cultural interaction (Hamm et al., 2005) and add another layer of complexity to friendships. Further, school counselors should reflect on these variables, as well as their own worldview and cultural values (see Yeh & Pituc, Chapter 5, this volume), when mediating peer conflicts.

Social Networks

The social ecology of students extends beyond individual relationships with peers into larger social networks. Brown (1989) classified these systems of peer interaction into three categories: dyads, cliques, and crowds. One-on-one dyadic relationships (e.g., friendships and romantic relationships) are the smallest units of the complex social network. The other two dimensions, *cliques* and *crowds,* become a discernable part of the social landscape beginning in late elementary school and into adolescence, facilitating students' navigation toward status and identity in an increasingly larger pool of formerly unfamiliar peers (Brown). Taken together, this tripartite model of social interaction creates a powerful dialectical source of influence in which social networks and individuals continually impact each other. Friendships and romantic relationships are addressed elsewhere in this chapter. Thus, this section of the chapter will discuss the influence of crowds and cliques as parts of students' social ecology on their interpersonal relationship development.

Crowds

Crowds are large, *reputation-based* groups, made up of individuals who are similarly stereotyped regarding attitudes and behaviors. The concept of crowds emerges into consciousness in preadolescence, likely due to the higher cognitive functioning necessary to create these heuristics (Brown & Klute, 2003). Examples of crowd labels include jocks, brains, druggies, normals, music kids, loners, and other categories or hybrids. The types of crowds in a school vary depending on the social context and community. For instance, multiethnic communities may utilize ethnic labels (e.g., Puerto Ricans or Polish), while British schools might lack a "jock" crowd (Thurlow, 2001). Crowds serve as reference groups for adolescents and may even channel friendships with in-group members (Urberg, Degirmencioglu, Tolson, & Halliday-Scher, 2000), although individuals belonging to the same crowd may not necessarily have close friendships exclusively within that crowd.

Outcomes associated with crowd affiliation. Crowd affiliation appears to impact students' well-being and adjustment, thereby warranting attention by clinicians. Psychosocial adjustment has been linked with crowd status, with high status affiliations related to higher levels of self-esteem (Brown & Lohr, 1987) and lower levels of social anxiety and depression (La Greca & Harrison, 2005). On the other hand, dysphoric characteristics were demonstrated in students who were rated negatively by peers and who held negative self-perceptions of their own status (Kistner, Balthazor, Risi, & David, 2001). However, there is some evidence that suggests belonging to a crowd, no matter the status, may have protective effects (La Greca & Harrison).

What about students who do not seem to fit into any category? Not belonging to a group may have consequences as well because crowd affiliations presume characteristics of one's identity. Fortunately, the individual's perspective on personal status can mitigate possible negative effects to the self-concept. Students who were outsiders, yet did not care about their status, demonstrated more positive psychological well-being than their fellow low-status peers who assigned importance to being part of a crowd (Brown & Lohr, 1987). The interpersonal associations a student is presumed to have and his or her perception of this status should be considered in counseling interventions.

Crowds and stereotypes. The projected images of various crowds naturally give rise to positive and negative stereotypes, which may be internalized by the individual and/or impact the way in which peers interact with each other. The assignment of certain labels may cause distress for some students. Unfortunately, mobility between crowds proves difficult, as membership is not voluntary, but rather assigned. Mobility not only relies upon individuals changing their own attitudes and behaviors but also necessitates change in the perceptions of their peers (Brown, 1989). For example, a student who is known as an antisocial "druggie" may participate in an intervention and/or decide to change his or her behavior, yet may find it difficult to socialize with peers who insist on treating him or her as a deviant. Alternatively, a male "jock" who is gay or questioning his sexual orientation may feel heightened pressure

to conform to traditionally male gender expectations and heterosexist norms.

Such prejudices may also have implications for a student's perceived self-efficacy, leading to underestimation of his/her potentials across multiple competencies (Aronson & Inzlicht, 2004; Bandura, 1977). While some studies have suggested that the importance of crowd affiliation tends to diminish toward the end of adolescence (Brown, Eicher, & Petrie, 1986; Brown & Klute, 2003), the long-lasting effects of labels may persist as students encounter future social situations. Consequentially, it is imperative for school counselors and educators to attend to the attitudes and behaviors reinforced by the peer network. More systemic group and schoolwide interventions aimed at psychosocial issues such as identity formation, stereotyping, conflict, teamwork, and respect may be more appropriate in addressing the powerful influence of peer crowds and cliques. The second half of this chapter describes examples of these interventions and highlights some programs with evidence of positive outcomes.

Cliques

Clique formation and stability. Cliques are uniquely *interaction-based* groups, composed of anywhere from 3 to 10 members who consider the clique to be their primary source of interaction among peers. Unlike crowds, cliques form based upon voluntary interaction patterns between students. Cliques tend to be homophilous in demographics such as age, gender, and race/ethnicity, although they gradually move from same-sex groups to mixed-sex groups as they grow older (Connolly, Craig, Goldberg, & Pepler, 2004; Dunphy, 1963). Research in multiethnic schools has shown that tighter-knit cliques were less likely to be ethnically heterogeneous (Zisman & Wilson, 1992) and that students of color were more socially isolated than White students were (Zirkel, 2004). School counselors looking to facilitate positive peer relationships among diverse populations must take into account the existence and implications of the school's racial–cultural dynamics, as well as their assumptions and biases. Clique dynamics and racial–cultural dynamics are likely to be intertwined.

Similar to peer crowds, cliques become prominent in later years of development, although as early as preadolescence (Adler & Adler, 1995). In earlier school years, children tend to associate with fewer peers, based on proximity. As they get older, children and adolescents encounter a wider variety of peers as they transition into middle and high school, as well as through extracurricular activities. These changes in social context can result in shifts in individual identity, friendships, and group memberships.

Although the cliques themselves tend to be stable over time, membership and social positioning within cliques frequently changes (Adler & Adler, 1995; Eder, 1985; Ennett & Bauman, 1996; Shrum & Cheek, 1987). Social network analysis research has found that there tend to be three roles within a clique structure: (1) *member* (i.e., associates with primarily one friendship group), (2) *liaison* (i.e., has links with a member of more than one clique or other liaisons, but is not a clique member), and (3) *isolate* (i.e., has few or no links to peers in cliques (Ennett & Bauman). Over time in late adolescence, it appears that cliques become looser in membership, incorporating greater numbers of individuals with few or no links to cliques (i.e., isolates) and those with multiple affiliations (i.e., liaisons) in addition to core members (Ennett & Bauman; Shrum & Cheek). Dunphy's (1963) seminal ethnographic study on Australian peer networks demonstrated how cliques also change in their gender composition, from same-sex groups to mixed-sex groups, as clique members begin to date each other and their groups merge. The sometimes transient nature of clique membership feeds clique dynamics which have implications for the relationships between students and the psychological adjustment of the individual.

Clique stratification and dynamics. Qualitative study of cliques provides a vivid glimpse into the developmental changes of intricate clique dynamics and stratification—both within and between cliques (Brown & Klute, 2003). P. A. Adler and P. Adler's (1998) six-year study of fourth, fifth, and sixth graders demonstrated how early adolescent peer cliques are stratified by status and prestige. Four main strata were found (in descending order of status): the *popular clique* (the most exclusive and highest in status), the *wannabes* (who hung around the popular clique in hopes of inclusion), the *middle group* (smaller, independent friendship circles), and *social isolates* (who tend to spend most of their time independently (Adler & Adler, 1998).

The popular clique's status in the hierarchy often dictated ways in which students related to each other. Those lower in status often were subject to antagonism by popular peers, yet the wannabes tolerated these imbalanced relationships and often went to great lengths (e.g., carrying out favors, belittling other students lower in status) to fit in with and be accepted by the popular clique (Adler & Adler, 1998). Middle groups of students, however, were more accepting of their peers and tended to be better adjusted (e.g., had better self-concepts) than the wannabes and social isolates who were preoccupied with moving up in status. Social isolates endured the most teasing and rejection from all levels of peers; they were often forced to play alone or eventually allied with other stigmatized peers.

Early adolescent peer cliques are also characterized by dynamics of power maintenance and domination motivated by popularity. Leaders of popular cliques often vacillated

between derision and temporary acceptance of followers and peripheral members seeking acceptance (Adler & Adler, 1995), seeking to keep their own elevated status. Those ranked lower in status within the popular clique as well as wannabes ingratiated themselves to the leaders in hopes of upward mobility. When working with students in early adolescence, school counselors should investigate the student's clique experiences. The desire to be a part of a certain clique and/or the threat over being displaced from one's current clique may create a great deal of stress to the individual. Additionally, he or she may experience negative relational patterns such as coercion and aggression as a function their place in the social hierarchy.

In middle and late adolescence, clique experiences become less antagonistic and focused on popularity and power. Although some cliques are more popular than others are and there may still be leaders/followers within the clique, the culture of rigid control by leaders and derision seems to be less prominent in middle and high school (Brown & Klute, 2003; Eder, 1985). Peer cliques in late adolescence particularly serve as a sort of home base, providing social support to their members and little concern with "who's in" and "who's out" (Brown & Klute). Interventions will likely focus on the dyadic level, rather than examining clique systems.

The Influence of Social Networks

Social networks have the potential to influence students strongly through norms. However, it is noteworthy to distinguish between the formation and maintenance of norms within peer crowds and cliques. Crowd norms are imposed from outside the group based upon perceived stereotyped attitudes and behaviors. Conversely, clique norms are formed within the group. Further, clique membership hinges upon one's ability to conform to the group norms (Brown, 1989). Concerns about fitting in and acceptance, highly salient in childhood and early adolescence, create conditions under which students are likely to be influenced by their peers.

Peer influence and antisocial behaviors. Another area of concern and interest is the influence of peer groups on antisocial behaviors, such as smoking or sexual activity. Prior research has shown that greater individual substance use is associated with greater use within the peer social network (Bauman & Ennett, 1996; Downs & Rose, 1991). Some studies are aimed at differentiating the influences of the various peer contexts (i.e., friendships, cliques, or crowds). One study (Hussong, 2002) found that adolescent substance use was most strongly predicted by a best friend's use (e.g., a student was more likely to smoke if he or she had a friend who did). Usage in the student's clique moderated the effects of best friend's usage as well—if the clique used more than a best friend, there was exacerbated risk, and if the clique used less than a best friend, there were protective effects (Hussong). It appears that one's peer affiliations have the power to influence behaviors both positively and negatively.

We must also note that several studies suggest that research and conventional folk wisdom runs the risk of overemphasizing the influence of peers on substance abuse and overlooking individual factors. The most cited alternative explanation is the adolescent's selection of friends and membership into cliques who exhibit certain behaviors (e.g., students who smoke tend to pursue friendships with other smokers). Research showing that cliques play a greater influence in the maintenance, rather than the onset, of antisocial behaviors corroborates the selection hypothesis (Ennett, Bauman, & Koch, 1994). Additionally, when asked to report the behaviors and attitudes of friends, students tend to project their own traits onto their friends (Bauman & Ennett, 1996).

Peer pressure. Conformity and resilience against peer pressure seem to mediate the effects of peer pressures. A study regarding high school drinking and its consequences (Arata, Stafford, & Tims, 2003) found that individual susceptibility to peer pressure was highly correlated with binge drinking (Urberg, 1992). Cultural factors also seem to mediate students' susceptibility to peer pressure. For instance, Black youth have shown lower levels of peer pressure and a need for peer approval when compared with White youth (Giordano, Cernkovich, & DeMaris, 1993). Adolescents of Mexican origin, whose families had most recently immigrated to the United States, demonstrated more resistance to peer pressure, perhaps influenced by Mexican cultural values related to a stronger identification with family as opposed to friends (Umaña-Taylor & Bámaca-Gómez, 2003). Therefore, interpersonal interventions should examine the interplay between individual characteristics (e.g., values, background, and attitudes) and the norms of the peer group.

Little has been studied in terms of the emotional response to peer pressure (Lashbrook, 2000). Qualitative study regarding the experience of peer pressure may provide insight into the psychological costs of conformity for students. For example, in Lashbrook's study regarding conformity to alcohol use, themes regarding fear of isolation, ridicule, and inadequacy emerged. Although the sample was composed of all White, college-aged students in a rural area, the implication that there is an affective consequence to peer pressure suggested that cognitive and behavioral interventions and programs (e.g., "Just Say No") may prove inadequate (Lashbrook).

Social Rejection, Withdrawal, and Isolation

At a time when peer acceptance is so important, the interpersonal experience of the socially rejected child or adolescent can be difficult and unsatisfying. What does it mean for a student to be "rejected?" Sociometric research utilizes peer nominations and ratings to categorize individuals within a context into one of five categories: popular, rejected, neglected, controversial, or average. Students who receive the highest number of negative nominations and ratings are categorized as "rejected." Researchers have naturally taken interest in the possible consequences of this status. Conventionally, the outcomes associated with a lack in peer acceptance have been thought to manifest in mid- to late childhood (Boivin, Hymel, & Bukowski, 1995; Ladd & Burgess, 1999). However, at least one study suggested that as early as kindergarten, rejection was linked to subsequent low self-confidence in the first grade (Phillipson, Bridges, McLemore, & Saponaro, 1999).

In studies focusing on mid- to late childhood, students with low peer-rated status have been found to be more aggressive and withdrawn and less sociable and cognitively skilled (Newcomb, Bukowski, & Pattee, 1993). Students who are rejected also experienced more academic, externalized (e.g., "acting out," dropping out of school, criminality), and internalized (e.g., self-esteem, anxiety, depression) problems (Bagwell et al., 1998; Coie, Terry, & Hyman, 1992; Coie, Terry, Lenox, Lochman, & Hyman, 1995; DeRosier, Kupersmidt, & Patterson, 1994; Panak & Garber, 1992; Parker & Asher, 1987). While these general tendencies are common to most rejected students, not all rejected students respond to being rejected in the same way. Many studies point toward two different subtypes: *aggressive-rejected* and *withdrawn-rejected* (McDougall, Hymel, Vaillancourt, & Mercer, 2001).

Aggressive-Rejected Students

Some studies indicate that aggression, in combination with rejection, predicts greater academic difficulties (Kupersmidt & Coie, 1990; Wentzel & Asher, 1995), higher levels of inattention and hyperactivity, and lower levels of prosocial skills (Bierman, Smoot, & Aumiller, 1993). In the extant literature, aggressive-rejected students were uniquely characterized by their difficulties with externalized outcomes. Aggression plus rejection correlated with later delinquency, more serious offenses, dropout, and physical acting out (Coie et al., 1992; Coie et al., 1995; French & Conrad, 2001; Kupersmidt & Coie, 1990; Miller-Johnson, Coie, Maumary-Gremaud, Lochman, & Terry, 1999). However, each of these consequences appears to be more severe for boys than for girls (Coie et al., 1995; McDougall et al., 2001). Rejection alone appears to be a stronger predictor of delinquency for girls (Miller-Johnson et al., 1999). These gender differences may be due to the operationalization of aggression in studies that are stereotypic for males. Females, on the other hand, tend to engage in *relational aggression* (see Chapter 40, this volume), which involves causing harm by intentionally hurting feelings, tainting reputations, and damaging relationships (e.g., teasing, spreading rumors, and exclusion).

Withdrawn-Rejected Students

While students who are thought of as aggressive-rejected do not demonstrate internalized maladjustment (McDougall et al., 2001), the reverse is true for withdrawn-rejected students. There appear to be few to no externalized difficulties for withdrawn-rejected students. Rather than characterized by peers and teachers as aggressive, these students are seen as shy and passive (Bierman et al., 1993). Withdrawn behavior in students has uniquely been found to be associated with greater depression, feelings of loneliness, and anxiety (Hymel, Rubin, Rowden, & LeMare, 1990; Newcomb et al., 1993; Rubin, Chen, & Hymel, 1993; Rubin & Mills, 1988), particularly in withdrawn-rejected girls (Bell-Dolan, Foster, & Christopher, 1995). Interestingly, some studies suggest that students' feelings about being categorized into this status mediated the link between status and internalized outcomes (Valas & Sletta, 1996, as cited in McDougall et al., 2001; Panak & Garber, 1992). In other words, those who were rejected *and* felt bad about it tended to feel greater anxiety, loneliness, and depression than those who were rejected but did not care.

Peer Relationships of Rejected Students

By virtue of a students' peer-assigned rejected status, the nature of their relationships with their peers warrants close attention. In Leary, Kowalski, Smith, and Phillips' (2003) examination of 15 events of school violence from 1995–2001, interpersonal rejection was involved in most cases. Of the cases, 12 involved a pattern of ongoing teasing, bullying, or ostracism. The U.S. Secret Service and Safe School Initiative data show that over two thirds of the recent school shootings have been associated with bullying, ostracism, and social rejection (Vossekuil, Reddy, Fein, Borum, & Modelski, 2000). Rejection from peers in adolescence tends to take on these chronic forms of victimization (Leary et al., 2003).

While rejection of peers can begin in early childhood, this kind of victimization does not seem to become salient until mid to late childhood (Boivin et al., 1995). Not every case of peer victimization toward rejection results in vio-

lence, but the possible volatile consequences behooves clinicians and researchers to pay attention to the way in which rejected students are treated by their peers (for a more comprehensive discussion of peer victimization and bullying, see Swearer, Buhs, Siebecker, Love, & Miller, Chapter 40, this volume).

Interpersonal relationship development, particularly in close interpersonal relationships, is another potentially troubling area for socially rejected children. There is contradictory evidence regarding the friendships of rejected students. Some studies indicate that rejected students have just as many friends as average children (Bagwell et al., 1998; Ladd & Burgess, 1999), while others indicate they have fewer close friendships (Brendgen, Little, & Krappmann, 2000; Kupersmidt, DeRosier, & Patterson, 1995). Researchers indicate that, despite the numbers of friendships that rejected students have, these friendships tend to be lower in quality with respect to mutual caring, conflict management, and intimate exchange (Parker & Asher, 1993). Conflict appears to occur at higher levels for students categorized as aggressive-rejected as opposed to simply rejected (Patterson, Kupersmidt, & Greisler, 1990). Interestingly, nominated friends viewed the relationship as lower in quality than the rejected students themselves did (Brendgen et al., 2000). Preserving these interpersonal relations with rejected students should be of import to school counselors, given the protective functions of friendship with respect to victimization (Hodges et al., 1999) and aggressive behavior (Ladd & Burgess, 1999, 2001).

In addition to tenuous friendships, rejected students tend to be peripheral members (i.e., less central and influential) of smaller cliques with other low-status peers (Bagwell, Coie, Terry, & Lochman, 2000). Bagwell and colleagues suggested that less central clique members may engender greater conformity to antisocial behaviors in hopes of greater acceptance or to achieve higher status within the clique. As aforementioned, the influence may very well be bidirectional: Students may self-select to be part of deviant peer cliques *and* the clique's norms may influence the student. In either situation, researchers have pointed out that deviant cliques membership may reinforce maladaptive, antisocial behaviors while precluding development and rehearsal of prosocial behaviors (Bagwell et al., 2000; Patterson, Capaldi, & Bank, 1991).

Contributing Factors to Rejected Status

One possible attribution of the rejected status may be due to perceived poor social skills (Newcomb et al., 1993). Aggressive-rejected children exhibit antisocial behaviors such as responding to ambiguous social situations with aggression and hostility (Dodge & Coie, 1987; Wood & Gross, 2002), while nonaggressive-rejected students may be seen by peers as socially awkward, incompetent, or strange (Bierman et al., 1993). Rejected students have also been found to have trouble monitoring their own strong emotions, as well as those of peers (Miller-Johnson et al., 1999). It seems that rejected students may not have developed the acumen for reading interpersonal cues, such as being able to recognize that they are upsetting their peers by being too bossy or persistent. Zakriski and Coie (1996) also found that while aggressive-rejected children were able to identify negative feedback directed at someone else, they tended to overlook negative feedback directed at themselves.

Theories describing rejection as incidental to individual characteristics, taken together with models theorizing sources of causality (McDougall et al., 2001), may be useful for clinicians to consider when choosing interventions or targeting student populations. For example, Parker, Rubin, Price, and DeRosier (1995) proposed a *transactional* model, which integrates predisposing factors, negative social behaviors, negative beliefs about the self and others, and peer relationships. It would be useful to consider all of these factors to come up with possible areas of intervention. For instance, Sandstrom and Coie (1999) found that fourth and fifth graders who were previously rejected tended to improve in status when they became more involved with extracurricular activities, when they developed better ideas of locus of control, and when their parents monitored the social activity of their peers.

When considering the way in which peers view or treat other students, various cultural factors inevitably come into play as well. For example, students may be viewed negatively because they are more reticent than other students are. Yet, their cultural values may prescribe silence as a form of respect; they may have learned that one should talk only when necessary. Difficulties in communication due to limited English proficiency may be misinterpreted as antisocial behavior. More generally, students who are "different" from the majority are susceptible to rejection by peers or differential treatment teachers and other school personnel. For example, a study of kindergarteners found that in the transition to first grade, Black children were more likely to experience chronic peer rejection and less likely to receive social support from their teachers and friends than were their White peers (Ladd & Burgess, 2001). It may be that the communication styles and ways of relating for Black children are viewed as "antisocial" or "inappropriate" (Sue & Sue, 2003) to their culturally different teachers or peers. Children with disabilities are particularly at risk for rejection, especially given that establishing and maintaining close friendships can be difficult (Brinton & Fujiki, 2002; Fukiji, Brinton, Hart, & Fitzgerald, 1999). Discrimination based on differences from the majority culture can have unfortunate outcomes for students, and

counselors and educators have a responsibility not only to facilitate positive peer relations and a climate of respect for all students but also to be an advocate for those historically oppressed (Sue & Sue, 2003).

Dating and Romantic Relationships

The prominence of dating and romantic relationships in childhood and adolescent life are very important as evidenced by their depictions in popular culture through music, movies, and television. Mass consumption of popular culture depicting adolescent dating and romance speaks to how these issues resonate with the highs and lows of these experiences in adolescent life. Yet, the corpus of research into these issues is new (Furman, Brown, & Feiring, 1999). Researchers have only recently stressed that these interpersonal relationships are more than trivial matters in adolescence (Collins, 2003).

Characteristics of Dating and Romantic Relationships

In this section, we discuss the unique dynamics and consequences of dating and romantic relationships on interpersonal relationship development. A romantic relationship, defined as "an ongoing pattern of association and interaction between two individuals who acknowledge some connection with each other" (Brown, Feiring, & Furman, 1999, p. 3), is different from all other close relationships in its voluntary nature and element of attraction (Brown et al., 1999). There are usually intense and passionate, although sometimes fleeting, feelings which may include sexual attraction (Brown et al.; Larson, Clore, & Wood, 1999). Attraction usually extends beyond mere sexual chemistry, however, and encompasses companionship, intimacy, and caring in a way different from friendship.

It should be noted that certain hallmarks of dating (e.g., autonomy in choosing whom to date, public displays of romantic affiliation, and sexual behavior) reflect Western norms. One's personal, religious, or cultural background may preclude many of these experiences or cause distress for the student and his or her partner. For example, romantic relationships are thought to help establish autonomy and individuation from parents (Gray & Steinberg, 1999), which may lead to intergenerational conflict between parents and children. Similarly, partners from different cultural backgrounds may have contrasting relationship expectations and consequently experience distress.

Conventionally, adolescent relationships have been thought of as transient and frivolous (Collins, 2003); however, current research shows that may not be the case. About 20% of adolescents 14 years old or younger, 35% of 15- to 16-year-olds, and almost 60% of 17- and 18–year-olds reported romantic relationships lasting 11 months or more (Carver, Joyner, & Udry, 2004). There is great variation between age groups regarding what constitutes feelings such as "being in love" (Bouchey & Furman, 2003). Research regarding externalized behavior, internalized outcomes, and academic achievement (Brendgen, Vitaro, Doyle, Markiewitcz, & Bukowski, 2002; Neemann, Hubbard, & Masten, 1995) correlated these negative outcomes with early adolescent relationships. These findings suggest that late adolescent students may be more developmentally equipped for romance and dating, regardless of their subjective experience of romantic feelings.

Counseling interventions may be aimed at developing the interpersonal and cognitive skills relevant to successful romantic relationships. Healthy romantic relations rely on secure relationship style (Furman & Simon, 1999), capacity to give and receive intimacy (Collins & Sroufe, 1999), and adequate management of emotions (Larson et al., 1999). Formal operations cognitive skills such as perspective taking and negotiating hypothetical situations also become increasingly important. Working on these prerequisites to healthy romantic relationships will likely prove valuable in enhancing the student's other interpersonal relationships as well.

In addition to the euphoric feelings of being involved with another person, dating and romantic relationships provide the context for many other benefits. These relationships provide an opportunity for experimentation of roles and ways of behaving (Furman & Simon, 1999) and can serve as precursors to adult relationships (Sullivan, 1953). Dating may also be a way of gaining social leverage, increased popularity, or affirmation from peers (Brown, 1999).

The adage "you can't have love without pain" seems to ring true in the preadolescent and adolescent years, even in the shortest of relationships. Studies have demonstrated that students who had broken up with a partner in the last 6 months reported more externalizing symptoms (Kuttler, La Greca, & Prinstein, 1999), and the stresses of managing a romantic relationships can lead to greater depressive affect (Davila, Steinberg, Kachadourian, Cobb, & Fincham, 2004; La Greca & Harrison, 2005). Further, being in a relationship can consume great time and energy, possibly sacrificing academic performance (Brendgen et al., 2002) or the quality of friendships and relationships with others (Connolly & Goldberg, 1999).

Students who identify as gay, lesbian, or bisexual or those are still exploring their sexual orientation face additional stressors (Diamond & Savin-Williams, 2003; Diamond, Savin-Williams, & Dubé, 1999). Internal struggles over their identities may be exacerbated by the unique

interpersonal challenges of being in the sexual minority. For example, identifying potential partners can be difficult and even dangerous in a homophobic community. Those currently in gay or lesbian relationships may also lack the social support of friends and family members. Moreover, the student may be distressed about how his or her sexual orientation will be accepted by the community at large. Counselors should keep in mind these unique factors when developing interpersonal interventions with gay, lesbian, and bisexual youth.

Dating and Romantic Relationship Expectations and Influences

Popular culture reflects the value of dating and romance as part of the normative adolescent experience. As a result, those who are not involved in a romantic relationship may experience anxiety and dysphoria (La Greca & Harrison, 2005). Adolescents currently dating or in a romantic relationship may also experience incongruities with their expectations (Connolly & Goldberg, 1999; Furman & Simon, 1999), often idealized in the media (Connolly & Goldberg). Counselors working with students on romantic relationships should differentiate exploring what they expect from actual/potential partners from the relationship itself.

The role of parents and peers in romantic relationships should be considered, as they are strong socializing forces for adolescents. Parents often directly influence certain relationship decisions, including who is acceptable to date, especially in non-Western traditional cultures and religions (Bouchey & Furman, 2003). Parents also indirectly affect the construction of representations of close relationships through their style of caregiving (Furman & Simon, 1999) and modeling of important interpersonal competencies (e.g., communication skills, conflict resolution, and displays of affection; Gray & Steinberg, 1999).

Romantic relationships also form under the strong influence of one's peer social context (see Brown, 1999; Connolly & Goldberg, 1999). Norms of peer groups at the clique or crowd level possess the power to shape individuals' dating decisions, such as who is "unacceptable" or "desirable" to date given one's prescribed social status or image. At the dyadic level, friends serve as social supports through various roles. For example, a friend can buffer potential rejection by acting as a messenger between the two parties, facilitate communication in the nascent stages of a romantic relationship, or act as an arbiter of wrongdoing in order to comfort a jilted friend (Brown). The interpersonal relationships at play within dating and romantic relationships, therefore, extend beyond the couple in question. This intricate interplay deserves attention in both research and intervention.

Romantic Rejection

Rejection in dating and romantic relationships can also cause distress for adolescents individually or between the couples involved in romantic relationships. In Leary and colleagues' (2003) examination of 15 cases of school violence, at least 6 of the perpetrators experienced recent romantic rejection (i.e., breakups or being rebuffed). As aforementioned, individuals vary in their abilities to manage emotions (Larson et al., 1999), and this may have serious implications given the strong emotions elicited by romantic rejection. Downey, Bonica, and Rincón (1999) proposed a model of *rejection-sensitivity*, which is the tendency to develop anxious or angry expectations of rejection based on interactions with parents and peers. Heightened sensitivity to rejection is later transposed onto romantic relationships. Individuals who are highly sensitive to rejection may react to ambiguous cues with hostility, despondence, withdrawal, or other efforts at gaining acceptance, which may escalate into either initiating or tolerating a unhealthy relationship.

Downey et al. (1999) postulated that rejection-sensitivity places individuals at risk for utilizing violence or coercion (e.g., angry reactions) or enabling these destructive relationship patterns (e.g., anxious reactions). In fact, more than 25% of adolescents (Wolfe & Feiring, 2000), and anywhere from 9% to 45% of middle school children studied (Downey et al.) experienced dating violence or aggression. Dating violence is generally thought to encompass "any attempt to control or dominate another person physically, sexually, or psychologically, resulting in harm" (Wolfe & Feiring, p. 360). Such a broad definition lends itself to subjective interpretation especially in nebulous situations, and sometimes the two parties involved experience a situation differently. Techniques for handling these sensitive interventions follow in the second half of this chapter.

Peer Sexual Harassment

Interpersonal antagonisms centered around sexual themes in schools additionally take the form of peer sexual harassment. The American Association of University Women (AAUW; 2001) conducted a nationwide study of sexual harassment in schools and found that 8 of 10 students experience some form of unwelcome and unwanted behavior. The most prevalent types included sexual comments, jokes, gestures, or looks; being touched, grabbed, or pinched in a sexual way; and spreading sexually related rumors (e.g., calling someone "gay" or claiming so-and-so had sex; AAUW). Over one third of students reported their first experience of unwanted behavior in sixth grade or earlier, and the most common places reported were in halls, classrooms or the gym area, or outside on school grounds (AAUW). Many stu-

dents reported emotional consequences (e.g., feeling upset, angry, and embarrassed) and behavioral responses (e.g., avoidance of the perpetrator, becoming more withdrawn, and not wanting to come to school) to these experiences. Of those students affected, 20% said that they would tell no one, and only 20% said that they would tell a teacher or school employee (AAUW). Given the reality of peer sexual harassment in schools, the active promotion of positive peer relations should supplement school policies on harassment and remedial intervention.

Summary of Interpersonal Relationship Development

The previous discussion broadly addressed major issues related to interpersonal relationships among peers in schools including friendship; social networks; social rejection, withdrawal, and isolation; and romantic relationships. One limitation of the research on the development of interpersonal relationships among children and adolescents is the primary focus on school-related relationships. For example, students of color in lower socioeconomic statuses tend to be significantly influenced by nonschool networks (Dolcini, Harper, Watson, Catania, & Ellen, 2005). This finding, along with the acknowledgement of cultural and familial influences, may have implications for greater efficacy in more broad-based interventions (Dolcini et al.).

In addition, the ubiquity of technology and the Internet today provides the landscape for new dimensions to interpersonal relationships among youth. With about 87% of teenagers ages 12 through 17 using the Internet (Lenhart, Madden, & Hitlin, 2005), youth today connect with their peers, family, and the outside world in ways unimaginable even 5 to 10 years ago. Youth frequently interact with others online through instant messaging, e-mail, discussion boards, social networking sites (e.g., MySpace, Facebook, Friendster), and Web journals (also known as "blogs"). While the literature on the nature and implications of these "virtually" contextualized relations is still nascent and the virtual landscape is constantly changing, some existing research looks at online analogs to traditional peer relations phenomena such as bullying and relational aggression. Ybarra and Mitchell (2004) found that 19% of young regular Internet users were involved in online harassment as an aggressor, victim, or both. Online harassment takes on diverse forms ranging from directly communicating physical threats and rude comments between people to indirectly defaming others via online postings. Initial research into online aggression finds that there are similarities in the profiles of conventional and online aggressors/targets (i.e., individuals who are engaged both as a bully and as a target), specifically marked by psychosocial challenge. There is also suggestion that, like victims of conventional harassment, online harassment targets experience distress because of these incidents (Finkelhor, Mitchell, & Wolak, 2000). It appears then that current knowledge on conventional peer relations can inform work with youth regarding online interactions. At the same time, researchers and practitioners should also investigate the unique nature and consequences of this ever-changing Internet peer culture.

Interpersonal Intervention Strategies

The remainder of this chapter will focus on intervention strategies within schools that will address the aforementioned areas of interpersonal relationship development, some in more detail than others. Some of the interpersonal interventions discussed in this section are more general in nature although some general interventions can be tailored toward more nuanced concerns regarding interpersonal relations. In particular, the intervention strategies that follow will emphasize enhancing students' interpersonal relationships with one another, school personnel, and their families. In an article summarizing intervention history within schools, Sandoval (1993) aptly defined the term *intervention* as "imposing a change or something new (an activity, strategy, or approach) in an already ongoing relationship between an adult (teacher, parent, administrator, and so on) and a child (or sometimes another adult) with the goal of improving it" (p. 195). He further indicated that interventions may also be directed at the internal state of the child, as well as toward observable behavior. Additionally, he noted that the purpose of an intervention is to bring about positive outcomes, particularly when negative ones might occur in the absence of an intervention. We would like to expand his definition to include targeting change in an ongoing relationship between two or more students as well. In other words, many times interventions aimed at improving interpersonal relationships will be directed at members of the student peer group.

Factors to Incorporate in Intervention Strategies

There are several factors to consider when planning and implementing interpersonal interventions within the school setting, including, but not limited to, culture, language, nonverbal communication, power, and developmental level of the student. Additionally, there is a wide range of interventions to choose from, growing out of various theoretical orientations and treatment approaches. This large repertoire demands that school counselors be well versed in all theoretical orientations and approaches offered within the

field of psychology (Sandoval, 1993). For instance, many intervention strategies grow out of the following schools of thought: developmental psychology, social psychology, learning, psycho-educational, humanistic, cognitive–behavioral, psychodynamic, neuropsychological, and ecological perspectives. Further, even when interpersonal issues are of primary concern, the focus of the actual interventions can vary as well, including emphasis on prevention, social behavioral problems, academic problems, family/parental issues, friendships, peer rejection and isolation, and romantic relationships/dating (Kratochwill & Stoiber, 2000). Additionally, in order to intervene effectively, school counselors must assess relevant influences within students' social world including peer group memberships and defining characteristics of various peer relationships. Further, school counselors must enlist the assistance of other adults to teach and reinforce effective interactions within students' various social contexts (Sheridan, Buhs, & Warnes, 2003). Finally, in order to determine if the intervention strategies are effective, school counselors must evaluate the interventions they choose to implement. It is imperative that school counselors, taking all of these issues into consideration, remain flexible and thoughtful rather than mechanistic or formulaic in seeking intervention strategies (Villa, Udis, & Thousand, 1994).

Culture

Regardless of the interpersonal issue or treatment approach, culture is an ever-present factor (Lee, 1995; Rogers & Lopez, 2002). School, family, and community environments are driven by their unique cultures, which children must learn to respond to appropriately and sometimes very distinctly (Bronfenbrenner, 1979a, 1979b). The importance of familiarity with multicultural counseling theory and research becomes clear when school counselors acknowledge the culturally embedded nature of children's behaviors, as well as the interventions developed to modify many of those behaviors (Kratochwill & Stoiber, 2000). In an effort to be multiculturally competent, school counselors must work toward increasing awareness of culturally diverse individuals and groups within the school system, as well as increasing the sensitivity of students, parents, and school personnel to cultural diversity (American School Counselor Association [ASCA], 2004; Crockett, 2003; Kwon, 2001).

Language and Nonverbal Communication

Like culture, language and communication are important variables to consider when implementing interpersonal interventions in schools. Communication involves sending and receiving messages, understanding, and being understood (Pedersen & Carey, 2003). Effective communication is impeded not only when native languages differ but also when the meaning of words and/or the way in which information is communicated varies according to cultural norms. Communication occurs not only through spoken word but nonverbally as well. Similar to spoken word, nonverbal cues may hold different meaning for individuals dependent upon cultural background and worldview (Sue & Sue, 2003). It is thus important for school counselors to be aware of various communication modalities and worldviews in order to effectively intervene when interpersonal difficulties arise.

Social Power

Social power is another important factor to consider when developing and implementing interpersonal interventions. Kehe and Smith (2004) defined *social power* as the "ability to expand or diminish opportunities for oneself and/or others" (p. 335). Smith, Richards, Granley, and Obiakor, (2004) described the invisible nature of power by noting that those who have the power often take it for granted without acknowledging its presence, while those who are denied access to power notice its absence. Power is present at multiple levels in all interpersonal interaction, and as a result, it is necessary for school counselors to recognize it, consider it, and address it in the development and implementation of all interpersonal interventions.

Developmental Level of Students

Finally, school counselors must also be aware of the developmental level of the student(s) with whom they are intervening. As described earlier in the chapter, the nature and quality of interpersonal relationships grow and change as children mature. Thus, interpersonal interventions that are appropriate for one age group are likely not appropriate for other age groups. With all these factors in mind, let us turn our attention to specific interventions that target interpersonal relationship difficulties within the school.

Individual Interventions

School counselors may consider intervening with individual students. While individual counseling relationships may be developmentally based (i.e., assisting students to achieve their interpersonal potentials), most individual interventions will be reactive or remedial in nature (Schmidt, 2003). For instance, while individual interventions aimed at self-discovery and understanding oneself through one's own worldview might be of great benefit for healthy interpersonal development (Hoare, 1991; L. J. Myers et al., 1991), such interventions are not realistic

in schools where counselors have student caseloads in the hundreds (Pedersen & Carey, 2003; Schmidt, 2003). Instead, individual interventions that are more plausible may include cognitive–behavioral-oriented approaches, which are remedial, developmentally appropriate, short-term, and solution-focused (J. E. Myers, Shoffner, & Briggs, 2002; Prout & Prout, 1998). Regardless of the nature of individual counseling relationships, key to the success of such interventions is that counselors model positive interpersonal interaction patterns with their students. This modeling can occur with children of all ages, from elementary to high school, although it is likely to occur in differing fashions for the various age levels.

Since individual interventions rely primarily upon verbal exchange, individual counseling typically occurs with older students. In fact, Thompson and Rudolph (2000) argued that verbal skills are not the only key component to effective individual counseling relationships, but behavioral maturity and cognitive development are needed as well. Behavioral maturity enables students to sustain attention and focus on a single issue, while sufficient cognitive development ensures that students are able to understand the relationship between their behaviors and associated outcomes. Examples of individual interpersonal interventions with middle school and high school age children might include those aimed at reducing antisocial behavior patterns, typically focusing on the behavior and skills of the student in question (Farmer & Cadwallader, 2000). However, given the powerful impact of peer relationships as previously discussed, such interventions may not succeed without supplemental interventions emphasizing changing the social context within which the behaviors typically occur inclusive of peer affiliations, classroom social structures, and social role supports within the school (Farmer & Cadwallader, 2000; vanManen, Prins, & Emmelkamp, 2004). Such interventions will be described in more detail in the following section.

Sexual harassment issues many times require individual intervention. When addressing concerns regarding sexual harassment, it is important that counselors foster an atmosphere/environment of mutual respect. This issue may lend itself well to the principles and approaches of Gender Aware Therapy, which focuses on social customs and expectations that influence one's development as a member of a particular gender (Gilbert & Scher, 1999; Good, Gilbert, & Scher, 1990). Gilbert and Scher recommended specific responsive intervention techniques when counseling individuals who have experienced sexual harassment. Their recommendations include (a) validation of feelings (feelings are appropriate, not an overreaction); (b) validation of harassment (sexual harassment is a form of sexual discrimination; one's rights have been violated); (c) framing the experience (sexual harassment arises from abuse of power, not physical attraction; it is not self-induced); and (d) developing effective strategies (determining healthy ways to process the emotional experience and manage any remaining interactions as a result of legal actions, if any). Clearly, these interventions are most likely to occur with high school students.

Individual counseling can be effective with elementary children when it emphasizes counselors modeling effective interpersonal interactions, as well as nonverbal interactions. Play therapy and art therapy are techniques that might be useful for school counselors working with elementary children. Through these nonverbal modes of communication, the counselor may be able to gain information that may be useful in informing alternative intervention strategies for these youngsters. Additionally, particularly for children experiencing interpersonal difficulties in other relationships in their lives, many times, they are able to benefit from the individual counseling relationship by developing a trusting relationship where they can communicate in an effective and nonthreatening manner (Nemiroff & Annunziata, 1990; Peterson & Hardin, 1997; Webb, 1991).

Interventions with elementary students may be delivered by noncounseling personnel as well. For instance, in an effort to mediate the effects of peer rejection, Buhs and Ladd (2001) recommended intervention early in the elementary school experience. In particular, they suggested that teachers encourage active classroom participation of all young children, as active engagement in classroom activities is related to better academic and emotional adjustment for students who are rejected by their peers.

Group Interventions

Although individual interventions can be effective with students, counselors are more likely to choose group counseling interventions to address students' interpersonal difficulties. Group counseling is an efficient way to address interpersonal concerns, as groups facilitate relationship development and positive interpersonal interactions (ASCA, 1999; Prout & Prout, 1998). Like individual interventions, group interventions can also be preventive, developmental, or remedial in nature. Again, like individual counseling, group counseling interventions are largely remedial in nature. For example, interpersonal group interventions can take on many shapes, such as focusing on activities (e.g., to build self-esteem), being problem focused (e.g., divorce), emphasizing social skills training (i.e., developing skills in specific areas of deficit, which can be generalized to behavior and interactions outside of therapy), as well as being structured as self-help groups (e.g., Alateen or Weight Watchers) or support groups (e.g., grief/loss;

Greenberg, 2003; Hansen, Nangle, & Meyer, 1998; Pedersen & Carey, 2003; Yalom, 1995).

Group counseling interventions typically brings together 6 to 10 students with similar concerns, focuses on a specific concern/issue, and has one or more counselors facilitating the group discussion, sometimes using curriculum and planned activities. Within each group, the counselor(s) establish a supportive and trusting environment among group members, direct the helping process, and facilitate the development of a group culture where students assist one another, both actively and passively. The development of the group culture is likely the factor that makes group counseling the most attractive way to intervene with students' interpersonal difficulties. As students engage in the group process, they become aware that others experience similar difficulties and that they are not alone in their struggles. Furthermore, with the assistance of the counselor(s) leading the group, the students are able to develop more effective ways of interacting with their peers, providing them with in vivo experience (usually success) of improving their interpersonal skills (Pedersen & Carey, 2003; Thompson, 2002). Examples of interpersonal group counseling interventions may include multiple sessions within a friendship skills group, where the focus of one session is on identifying attitudes and behaviors that generally result in making and keeping friendships. Such a session would be followed by another where the focus becomes addressing the kinds of attitudes and behavior that prevent the development of friendships. A later session might then bring the two previous sessions together and begin to personalize what the students have learned (e.g., "In what way am I impeding the development of friendships and in what way am I facilitating it?"; Greenberg, 2003).

There are few evidence-based group counseling interventions that have been implemented in school settings, and those that have tend to be limited in scope. Many group interventions have been developed in order to address interpersonal difficulties youngsters encounter, yet many of these interventions have not been located within school settings, but rather within community and clinical settings. Romasz, Kantor, and Elias (2004) argued that it is not only important to locate such programs within the school, but also ideal, as schools provide students with opportunities to both learn and practice social skills in an environment where academic instruction and personal life experience are intertwined. In other words, due to the interpersonally interactive nature of the school setting, by default students are given the opportunity to interact interpersonally with their peers both within and outside the structured group setting. Fisher, Masia-Warner, and Klein (2004) noted additional benefits of providing group interventions in the school setting including (a) making treatment more acceptable to children and families due to the context (no need for outside referral), (b) reducing common barriers for treatment including cost and transportation, and (c) increasing the likelihood of learned behaviors generalizing to the "natural" environment, as school is the environment where youngsters spend the majority of their time. Fisher and colleagues noted that it is very apparent that a gap exists between evidence-based interventions and services typically provided in schools. Further, they indicated of import at this point is determining which evidence-based programs can be effectively transported into school settings. Since there are limited examples of evidence-based school group interventions for counselors to draw upon, counselors are encouraged to look to community and clinical settings for evidence-based group interventions that can be transported into the school setting.

A few examples of group interventions that have demonstrated success within school settings do exist, but as previously mentioned, they tend to be limited in scope. Brief descriptions of these interventions follow. One example targeted toward the treatment of social phobia is Cognitive–Behavioral Group Therapy for Adolescents (CBGT-A), which focuses on psycho-education, cognitive restructuring, problem solving, social skills, and behavioral exposure and consists of sixteen 90-minute sessions (Hayward et al., 2000). Another example, also targeting the treatment of social phobia, is Social Skills Training (SST), which focuses on social skills training, exposures, problem solving, cognitive restructuring, and relaxation techniques and consists of 12 one-hour group sessions, each followed by a 30-minute practice of learned skills in a simulated environment (Spence, Donovan, & Brechman-Toussaint, 2000). A third example of a group intervention targeting the treatment of social phobia is Social Effectiveness Therapy for Children (SET-C), which focuses on behavioral exposure and social skills training and consists of 24 sessions delivered over a 2-week period (Beidel, Turner, & Morris, 2000) Two sessions are conducted weekly—one is an individual exposure and social skill training session, while the other is a group social activity. Fisher and colleagues (2004) modified the SET-C model for delivery to high school students, creating the Skills for Academic and Social Success program (SASS), which focuses on psycho-education, realistic thinking, social skills training, exposure, and relapse prevention and consists of 12 weekly group meetings, two group booster sessions, two brief individual meetings, and four weekend social events. Finally, a group intervention targeting at-risk children entitled Teaching Empowerment through Active Means (TEAM) focuses on teaching skills such as conflict resolution, anger management, responsible decision making, healthy interpersonal boundaries, managing unfairness, positive communication and listening skills, and respect (Redivo & Buckman, 2004). TEAM meetings typically consist of 90-minute sessions including an initial

"huddle up," a stretching/yoga routine, an activity requiring the group to work together, and a closing "huddle up." Of note, the TEAM approach has demonstrated effectiveness in encouraging cross-clique interactions, with lasting impact of at least two years following participation in the intervention.

It is important to note that while group counseling interventions are attractive strategies to utilize, there are difficulties inherent with their use (Schmidt, 2003). Counselors many times encounter scheduling obstacles, particularly when a group is being formed by students who have differing class schedules. Additionally, sometimes conflicts with teachers arise because of the disruption of classroom instruction that occurs by pulling students out of class to participate in a group. Although counselors strive to develop and implement interventions that are the least disruptive to the learning environment for students, it is inevitable that some disruption will occur. It is the counselor's job to minimize the disruption (Greenberg, 2003; Schmidt, 2003).

A nontraditional group counseling intervention that is more commonly found in school settings is structured programs that are integrated into classroom curriculum (Adalbjarnardottir, 1993; Fraser et al., 2005; Johnson, Johnson, Dudley, & Magnuson, 1995). For example, a group intervention aimed at improving children's social–cognitive competence and skills was introduced in elementary school classrooms (Adalbjarnardottir, 1993). Teachers were trained to deliver curriculum that emphasized social problem-solving skills such as generating alternative strategies, anticipating consequences, and selecting a "best" strategy. In addition to the formal curriculum, as social conflict occurs throughout the week, the teacher has the opportunity to work with the students to address the conflict in a constructive manner. Another classroom intervention is Making Choices: Social Problem Solving Skills for Children (MC; Fraser et al., 2005). MC was developed to promote social competence and reduce aggression. MC's instructional program focuses on teaching children how to encode and interpret social and environmental information, identify and manage feelings, and generate appropriate goals and responses in play and classroom interactions.

Finally, peer mediation training has been introduced at the classroom level, teaching children how to negotiate agreements and mediate fellow classmates' conflicts (Johnson et al., 1995). Students who successfully learn these strategies demonstrate advantages over others, such as being empowered to regulate their own behaviors, increasing their abilities to cope with stress and adversity, and developing and maintaining high quality interpersonal relationships with peers (Johnson et al.).

Another group counseling intervention that may be utilized to address interpersonal difficulties is family therapy. This is the least utilized strategy by most school counselors, due to time constraints, as well as difficulties in coordinating the schedules of counselors, students, and family members. Despite these difficulties, Sandoval (1993) asserted that family therapy is an intervention that targets an important system within which the child must function. Further, school counselors report family problems as the most frequent type of problem encountered in counseling relationships (H. T. Prout, Alexander, Fletcher, Memis, & Miller, 1993). As stated previously, there are times when the family's mode of operation and expectations are in direct conflict with that of the school. In these instances, the counselor's role is to mediate between the school and the family in order to increase the likelihood of reducing the interpersonal conflict and acting out behavior demonstrated by the student (Harrison et al., 2003). As modeling of appropriate interpersonal interaction styles is a key component to a youngster's learning regarding developing and maintaining positive and healthy interpersonal relationships, interventions with parents and family members can prove beneficial when the interventions serve to improve the social modeling that occurs within the family. As such, family therapy is not always necessary, nor the only way to intervene within families. Parent conferences with school counselors and/or teachers that address interpersonal issues such bullying or harassment may also be effective means of impacting the social modeling that occurs within the home environment. Additionally, offering educational programs to parents regarding common interpersonal difficulties encountered by students may not only serve to strengthen the relationship between the school and parents, but can also provide parents with much needed information allowing them to initiate informed discussions with their children regarding interpersonal relationship issues. Finally, a more structured approach to parent education might include models such as the Parent-Management Training (PMT) model described by Carolyn Webster-Stratton (1997). This model focuses on direct intervention with parents aimed at improving parenting skills, which in turn has demonstrated a reduction in student conduct problems, improved student social competence, and overall improvement in student functioning.

Schoolwide Interventions

In contrast to individual and group counseling interventions, schoolwide interventions are typically preventative in nature and offer an alternative strategy to school counselors, assisting them in promoting and facilitating positive interpersonal relationships to a wider audience (Romasz et al., 2004; Schmidt, 2003). For instance, educational assemblies on special topics (e.g., violence; peer pressure;

gender roles, expectations, and relationships; friendships; aggression and bullying; and sexual harassment) are useful means of providing information to a large group of students. Many times, this format can be very effective, particularly when the programs are interactive and multimodal in nature, involving the students in the audience (e.g., performance, role-playing, interactive games, and art-related projects; Close, 2005). Further, when ongoing classroom curriculum is developed to coincide with schoolwide programs, the structure, stability, and skill building focus in the classroom improves the effectiveness of the educational assemblies and schoolwide programming (Romasz et al., 2004). Braswell and colleagues (1995) asserted that schools are the ideal site for preventative interventions because of opportunities that naturally present themselves in the school setting enabling students, parents, and school personnel to interact collaboratively to achieve positive outcomes.

There is an increasing trend for the development and maintenance of social competency programs as schoolwide preventative intervention programs (Frey, Hirschstein, & Guzzo, 2000; Leadbeater, Hoglund, & Woods, 2003; Taylor, Liang, Tracy, Williams, & Seigle, 2002). Such programs grow out of social and emotional learning theories and are designed to create a safe and cooperative learning environment that promotes the intellectual, social, and emotional development of children (Taylor et al.). One such program, Reach out to Schools: Social Competency Program (SCP), is an elementary primary prevention program that consists of curriculum delivered to students in grades K–5 by the teachers in their classrooms (Taylor et al.). The yearly curriculum consists of 42 regular lessons and 32 supplemental lessons, implemented twice per week for approximately 15 to 30 minutes. Communication, self-control, and social problem solving are the three areas of focus within the curriculum, with the structure allowing students to address current classroom issues as well. Taylor and colleagues reviewed literature that provided support for this model by demonstrating beneficial effects of the program including improved social skills, a greater sense of self-worth and empowerment, increased classroom participation, more time spent on academics, and reduced problem behaviors.

Another schoolwide social competency program is Second Step, which consists of a violence-prevention curriculum that is delivered by teachers and school counselors from preschool through middle school (Frey et al., 2000). Second Step emphasizes teaching children perspective taking, problem solving, and anger management strategies, enabling students to decide "what to do"; as well as behavioral skills training, enabling students to rehearse specific steps for "how" to do it. Second Step also includes parent training in the form of six video-based instruction modules. Similar to Second Step, Steps to Respect: A Bullying Prevention Program (Frey et al., 2005) consists of school policy development and staff training to address adult and systemic factors, along with classroom curriculum promoting prosocial beliefs and social–emotional learning. This program is associated with decreases in bullying behaviors for students who engaged in bullying behaviors prior to intervention. Of note, 77% of children were observed either engaging in or encouraging bullying behavior at one point or another. Thus, successful intervention not only reduced active engagement in bullying behavior, but also the encouragement of bullying behavior as well (Frey et al.).

Finally, another example of a schoolwide social competency program is the Walk away, Ignore, Talk, and Seek help program (WITS; Leadbeater et al., 2003). WITS was developed collaboratively by elementary school teachers, community-based police officers, and a university-based psychologist with the goal of reducing school and classroom levels of victimization. Since its development, WITS has been widely implemented by various school personnel, community organizations, parents, and older students. WITS is an acronym that has been easily utilized to consistently convey to young children workable, developmentally appropriate strategies for managing conflict within peer relationships. Leadbeater and colleagues reported that utilization of WITS has been related to decreases in levels of relational and physical victimization, as well as increased levels of classroom social competence. Researchers argue that prevention programs such as those just described demonstrate the best results when a commitment to the underlying beliefs and practices of the program is adopted and enacted schoolwide (Frey et al., 2000) and if possible, within families and the community at large (Leadbeater et al.). In other words, social competency curriculum delivered in the classroom is most beneficial for students who consistently witness modeling and reinforcement of constructive problem solving by all school personnel, by their family members, and within the community.

Specific issues that may be prime for schoolwide interventions programs are interpersonal difficulties that arise within the peer social network. Similar to the larger sociocultural, community-at-large, school, and family contexts, peer social networks serve as one of the systems in which youth operate. As such, school counselors and researchers should develop and implement interventions pertaining to cliques and peer networks on a systemic level. These can take the form of schoolwide programs to facilitate teamwork, understanding, and respect among students of all different backgrounds and social circles. School counselors can implement groups or peer mentoring programs to address the issues of identity formation and peer pressure. Administrators, educators, and counselors can work together

to develop a service-learning component to existing curricula, which would encourage students to get out into the community and gain experience beyond their insulated social networks. The dearth of systemic, evidence-based interventions addressing the structure and dynamics of peer social networks behooves school counselors to implement and evaluate these types of programs.

Other Interventions and Various School Counselor Roles

Finally, counselors are likely to find themselves negotiating between various constituents in their students' lives to facilitate interpersonal relationship success. For instance, counselors take on roles in the school as liaisons, mediators, network therapists, and parent/family educators (Pedersen & Carey, 2003; Thompson, 2002). Additionally, counselors sometimes train students to provide peer mediation interventions with their fellow classmates. Further, counselors also provide training to teachers, school administrators, and other counselors.

Counselor as Liaison

As liaisons, counselors interface between the student and his or her family, the school, and the community in order to gain a better understanding of the student and to assist in improving a student's interpersonal interaction success with individuals at school, as well as outside of the school environment (Hiatt-Michael, 2001; Pedersen & Carey, 2003). In the role of liaison, counselors may become "cultural brokers" who attempt to educate various parties (e.g., parents, teachers) regarding alternative perspectives/worldviews and assist them in identifying and working toward mutually acceptable goals for the students (Gentemann & Whitehead, 1983; Sheridan et al., 2004). For instance, for children whose parents speak limited English or no English at all, communication between the school and home environment is at best difficult, if not impossible. Additionally, children in such situations many times not only serve as the interpreter between the family and school, but also find themselves caught between conflicting familial and school expectations or cultural norms. School counselors who take on the liaison role might locate a trained interpreter to assist with effectively communicating with such families. Then, once the student has been removed from serving as the interpreter, the counselor can effectively assess familial cultural norms and begin to educate parents regarding school cultural norms as well. As the counselor gains a better understanding of familial cultural norms, these norms can be communicated to the student's teacher(s), particularly when familial norms may be in conflict with school norms and/or expectations. As a relationship with the family is developed, the counselor can facilitate enlisting familial support for school goals, while acknowledging the importance of incorporating and/or accommodating for conflicting familial goals. Beyond serving as a liaison between the school and home environments, counselors as liaisons also develop networks and negotiate with organizations outside the school system. The development of these relationships many times increases students' access to and utilization of much needed community resources and services that cannot be provided by the school (Crockett, 2003).

Counselor as Mediator

When interpersonal relationship difficulties are at their worst, counselors are likely to take on the role of mediator between various parties. Many counselors are trained in conflict resolution strategies, which involve intervening with at least two individuals (perhaps more) who are experiencing conflict. Conflict resolution and mediation includes monitoring problematic interaction patterns and modeling effective interaction patterns, as well as direct intervention within social relationships and encounters. For instance, counselors may mediate conflict between students and teachers, teachers and parents, parents and students, parents and school administrators, and so forth. As a mediator, counselors attempt to reduce the participants involved in mediation to the bare minimum to increase the likelihood of conflict reduction, mutual understanding, and eventual conflict resolution (Pedersen & Carey, 2003). For example, in the role of mediator, the school counselor may be asked to settle a dispute between a student and teacher, where the student perceives his/her grade to be negatively impacted by factors other than academic performance. In the mediator role, the counselor would encourage both parties to communicate directly with one another and attempt to resolve their differences with minimal direct intervention from the counselor. The counselor's main role as mediator is to facilitate calm interaction between the parties and encourage utilization of positive problem-solving skills.

Counselor as Network Therapist

Another strategy that might be utilized by counselors in an effort to improve interpersonal relationships with a variety of parties in students' lives is Network Therapy. Network Therapy grows out of ecological models and emphasizes the importance of including the various contexts of students' lives when attempting to implement change (T. B. Smith, 2004). Such an intervention might include simulta-

neous intervention with students, family members, friends, teachers, and so forth. Intervening in this manner not only acknowledges the importance of the multiple contexts that students operate within (Bronfenbrenner, 1979b), but actually harnesses the power and influence of each of the contexts at the same time. For instance, some students may receive consistent feedback from friends, family members, teachers, and so forth regarding behaviors that elicit unwanted responses. While the student struggles to take in this feedback received during various individual encounters, which makes it difficult for the student to take ownership of his/her behavior and make efforts toward change, the message becomes more powerful when delivered by multiple important others all at the same time. The counselor who utilizes Network Therapy as an intervention strategy would invite the student and multiple members of the student's interpersonal relationship network (e.g., family, friends, and teachers) to meet together at one place and begin to discuss as a group common behavioral difficulties demonstrated by the student. It is highly likely that during the meeting time, the student will engage in the problematic behavior. When that occurs, it provides an in-the-moment example that can be discussed and explored by all members, with the guidance of the counselor.

Counselor as Parent/Family Educator

Another role common to school counselors is that of parent/family educator (DiCamillo, 2001). In this role, counselors intervene with the goal of improving parental participation in the academic and social lives of their children, as well as providing parents with the skills to effect behavioral changes in their children (ASCA, 2003). An example of such an intervention includes counselors conducting parent education classes and collaboratively developing strategies with parents to increase their involvement in the academic and extracurricular lives of their children. One such program might be an after-school tutoring program that includes the involvement of students, parents, and other school personnel. Such a program would not only address the academic needs of the students involved, but would assist the parents in becoming more familiar with school personnel, as well as the academic demands faced by their children, while at the same time providing students with the support, guidance, and expertise of the various school personnel involved in the program. In most cases, parent/family education occurs in a group setting and is tailored toward the parenting needs of the school in question. Thus, programming around specific issues (e.g., talking to your teen about sex, managing your child's anger) might be developed, announced, and delivered at parent–teacher organization meetings.

Peer Mediation

More and more frequently, counselors will train students in strategies that allow students to intervene with their fellow classmates (ASCA, 2000b). Peer mediation is a popular method of intervening with students experiencing interpersonal difficulties. Through peer mediation, trained students counsel and help facilitate the growth and development of other students through the use of their leadership skills (Buck, 1977), as well as through modeling behaviors within the interpersonal relationship that is developed between the peer counselor and student (ASCA, 2002b). A distinct advantage of the peer counseling relationship is that it provides students with positive interpersonal relationship experiences with peers at or near the same age (Salmivalli, 1999; Salovey, 1996). A variety of interventions can be offered through peer mediation, including one-to-one relationships with peers assisting with personal and academic difficulties; group interactions as group leaders, group counseling assistants, and trainers of peer-mediators-in-training; tutoring and educational consultant/assistant relationships; welcoming and orienting new students and parents to the school; and finally, serving in an outreach capacity to increase the awareness and understanding of the role of counseling and its services within the school (ASCA, 2002b).

Researchers agree that peer mediation is widely utilized within schools, despite limited research demonstrated its efficacy. Bickmore (2002) summarized recent research findings indicating that peer mediation programs are associated with a reduction in physical aggression and disciplinary actions. While acknowledging the dearth of available data, S. W. Smith, Daunic, Miller, and Robinson (2002) noted research findings indicate that, when peer mediation was utilized, (a) 85–95% of mediated conflicts resulted in lasting agreements and (b) referrals to school administrative personnel for inappropriate student behaviors decreased. Bickmore also reported that peer mediation programs are associated with improved problem solving, decision making, communication skills, critical thinking, conflict resolution, and self-discipline skills for those trained as peer mediators. Finally, the strength, sustainability, and effectiveness of peer mediation programs are improved when mediation teams are more diverse (i.e., academically, socially, culturally, and with regard to gender; Bickmore). Cunningham and colleagues (1998) argued that there are many potential benefits to implementing peer mediation programs including (a) students may be able to identify conflict and relational aggression more easily than adults; (b) since peer mediation programs span primary, middle, and secondary school years, they may be an important component of managing difficulties that arise at various developmental levels; and (c) given the relatively low cost, mediation programs are

affordable even when resources are limited. While there are many variations of peer mediation programs in existence, programs commonly include curriculum for defining the problem, exploring feelings, and negotiating solutions (Bell, Coleman, Anderson, Whelan, & Wilder, 2000).

Training of Professional Staff

In addition to training students, counselors may also conduct training sessions for teachers, administrators, and other counselors (Kirschenbaum, 2001). These sessions emphasize interpersonal skills that can be incorporated into classroom curriculum and schoolwide programming. Such topics might include emotional education and/or competence (Buckley, Storino, & Saarni, 2003; Goleman, 1995), character education (ASCA, 1998), and moral education (Elias & Clabby, 1992). Essentially, each of these topics targets teaching children how to get along with each other (Pedersen & Carey, 2003). The social–emotional learning and social competency program models that were just described in detail are examples of programs that grew out of teacher training. Once teacher training is complete, the curriculum can be introduced into the classroom as an intervention strategy.

Indirect Interventions

Finally, interpersonal interventions may be indirect in nature, in other words, not an actual intervention strategy, but rather an active creation of an environment that facilitates positive interpersonal relationships (ASCA, 2002a). For instance, obstacles to gender equality and the underlying attitudes and associated behaviors can be addressed through the use and modeling of acceptable language, organizational structure, leader selection, expectations of students, and the development and implementation of school programming. Counselor awareness, as well as the counselor's role in actively creating an inclusive and accepting environment, is particularly important when considering students' sexual orientations (D'Augelli & Pilkington, 2002). Sexual minority youth are more likely to encounter difficulties with the development of self-acceptance and healthy self-esteem, particularly when exclusive language, misinformation, stereotypes, and myths are allowed to be perpetuated (ASCA, 2000a). Thus, in instances such as these, school counselors should intervene proactively and in broad environmentally structuring ways, rather than with targeted, specific interventions, to assist with the healthy interpersonal development of all students. For example, when discussing intimate relationships, counselors and other school personnel who are actively creating an environment of inclusion would inquire about a student's "partner" or "significant other," rather than "girlfriend" or "boyfriend."

Interventions Summary

As has been demonstrated throughout the intervention section of this chapter, social modeling is the key to success when intervening with regard to any issue or utilizing any strategy or technique. Additionally, it has been highlighted that school counselors take on many roles and interact with many constituents in order to facilitate healthy interpersonal development for students. Counselors must respond not only to the needs of the school and its personnel but also to the larger environmental contexts within which students operate. As such, Galassi and Akos (2004) summarized the role of school counselors and the importance of their interventions well:

> The school counselor is a leader within the educational community who works with students, teachers, administrators, parents, and other members of the community to build a supportive learning environment that nurtures the development of academic, career, and personal/social competence among students and fosters an appreciation of diversity and a commitment to social justice. (p. 155)

Interpersonal relationships in the lives of students are complex and impact many aspects of their lives, including academic performance and overall mental health. Utilizing developmentally and culturally appropriate means, school counselors proactively and reactively intervene with students in efforts to facilitate optimal interpersonal development.

Evaluation of Programs and Interventions

Today's culture of accountability in our nation's schools mandates that school counseling follow suit in providing evidence for the field's effectiveness. However, school counselors have traditionally been absent in this trend (Green & Keys, 2001). It has been suggested that school counseling has lagged in evaluating its effectiveness for a number of reasons: inadequate knowledge of and training in assessment practices, ethical issues around confidentiality, time and funding restraints, and an overall lack of self-efficacy on the part of school counselors to conduct evaluations (Foster, Watson, Meeks, & Young, 2005). Further, even when evaluation is effective and demonstrates benefits, sometimes the data is not sufficient motivation for those implementing the programs. For example, many intervention programs target decreasing undesirable behaviors, which may not be readily apparent for teachers, in the midst of day-to-day experiences with students. As a result,

Frey and colleagues (2000) noted that the benefits of many primary intervention programs are not always apparent to those implementing the programs despite objective data indicating success. In the absence of subjectively observable benefits, teachers may lose the motivation to continue expending the time and energy necessary for successful implementation.

Evaluation practices will vary according to the type of intervention implemented. Foster and colleagues (2005) highlighted the applicability of a *single-subject research design*, which looks at repeated measurements of target behavior for an individual student or single group. By comparing baseline and treatment levels of target behaviors, the counselor/evaluator gathers data to determine the effectiveness of an intervention. While Foster and colleagues' suggested research designs call for the measurement of behaviors, it may be more salient in the area of interpersonal relationships to more broadly assess for both attitudes and behaviors which serve as markers for psychosocial functioning (e.g., depressive symptomology, quality of relationships, or experiences with conflict).

In light of the pressures to be accountable, formal evaluation theory cautions against taking a purely outcomes-driven approach, especially with respect to systemic programs and interventions. The result can be a "black box evaluation" in which there is a lack of an articulated program theory to explain what might be contributing to the outcomes and why (Rossi, Lipsey, & Freeman, 2004). Prior to implementation and evaluation of a program, evaluators should explicitly articulate its assumptions and expectations, service implementation plans, inputs or resources, and other factors which may be at play in the school and community contexts. Identifying these factors can help the counselor/evaluator to understand the results of an evaluation more fully. In fact, Romasz and colleagues (2004) argued for the importance of an action-research model, which "involves the testing of theories and models by putting them into practice, evaluating their impact, and using the results to refine future theory, method, and practice" (p. 94).

When conducting evaluations on systemic interventions, evaluators should also aim to look beyond traditional experimental field-methods for isolating a program's effect. One research design that provides a comprehensive alternative is the Extended-Term Mixed-Method (ETMM) (Chatterji, 2004). It is theoretically grounded and defined by five characteristics: (a) use of a developmental, long-term research plan, tracking the course of a program over the course of its life, beginning with formative needs assessments through to summative outcome evaluations; (b) use of systemic, contextually grounded methods in earlier studies followed by more analytical, quasi-experimental designs in later phases; (c) deliberate consideration of environmental variables as part of the research; (d) use of multiple research methods (e.g., quantitative and qualitative) to understand relationships and causality; and (e) explanation of causality based on empirical data and substantive knowledge gained on the program and its setting (Chatterji, 2004, p. 7). The ETMM method provides a systematic approach to conducting evaluations and allows evaluations to be grounded in the complex realities of school-based programs.

School counselors must begin incorporating the role of "evaluator" as an integral part of their functioning (Green & Keys, 2001). This entails including training and practice of assessment and evaluation in school counselors' ongoing professional development. One way that school counselors can bridge this current gap in knowledge and expertise is to build coalitions with other agents in the school system, including administrators, educators, school psychologists, school social workers, parents, and community leaders. This synergy of energy, knowledge, and expertise can better serve the field of school counseling and unite the shared goals of these stakeholders in ensuring the positive psychosocial functioning of today's students.

Conclusion

Given the profound effects of interpersonal relations on student achievement and development, school counselors should take measures to be acquainted with the vicissitudes of students' interpersonal relationships. This chapter has highlighted some prevalent issues relevant to the school-age years. Facilitating positive peer relations around these issues necessitates a wide repertoire of skills and knowledge for school counselors. School counselors must see beyond an individualistic, dyadic model and address both contextual and systemic factors, while bringing together research and practice. As school counselors, we must be proactive in promoting positive peer relations, for these are life-long developmental concerns.

XXXVII
SUICIDE PREVENTION, INTERVENTION, AND POSTVENTION

SHERI BAUMAN
University of Arizona

Introduction

Suicide-related crises (dealing with a suicide gesture or suicidal ideation) were two of the top four types of crisis situations encountered by a sample of school counselors (Mathai, 2002). They are also one of the most challenging and disturbing situations a school counselor ever faces, regardless of how much experience and training the counselor has. School counselors may be involved in all aspects of suicide, from prevention programs and activities to intervention with suicidal students, and unfortunately, with response services to students following a completed suicide. School counselors are important resources for students, educators, administrators, and family members who seek advice and expertise. "Counselors are on the front line for identification, prevention, intervention, and postvention of suicidal behavior. As oppressive as that may feel to counselors, it is nonetheless a fact" (Stefanowski-Harding, 1990, p. 334). The purpose of this chapter is to provide useful and current information for school counselors and counselor educators so that they might be better informed and prepared to address youth suicide.

Definition of Terms

Definitions of *suicide* convey the harsh reality of this behavior: self-murder, self-inflicted death, deliberate self-annihilation, self-destructive act with intent to die—these are among the definitions found in the literature (Stauffer, 2004; Stillion & McDowell, 1996). Suicide is usually a conscious, planned, and premeditated act, but it can also be impulsive and unplanned (particularly in adolescents), a desperate attempt to end unbearable pain. A suicidal event (gesture, attempt, or threat) may be what brings a student to the attention of the school counselor, but it is often the case that the reason for seeking help is something other than suicidal thinking. School counselors may also work with survivors of suicide (friends and loved ones of someone who completes an act of suicide), and when a student commits suicide, the school counselor must cope with his or her own personal loss while providing support to others.

The term *completed suicide* is used to accurately describe a death by suicide. The phrase *successful suicide* implies that this act can be an effective solution to a problem, and it should be avoided. *Suicidal ideation* refers to thoughts of suicide that are nonspecific as to plan or timing (e.g., "Sometimes I think I'd be better off dead"). The term *suicide gesture* describes an act that implies suicidal behavior but which is of very low lethality (e.g., making a very superficial cut on the wrist, taking five aspirin) and is intended to be a cry for help or a way to express the depth of pain an individual is experiencing. A *suicide attempt* is more lethal (e.g., taking a bottle of sleeping pills) and implies that the person believed their action would result in death (even if that belief was based on inaccurate information) and, if the individual survives an attempt, it is because someone intervened or interrupted the act. The *lethality* of a suicide attempt describes the likelihood that the action will result in death. Both thoughts and actions related to suicide are collectively referred to as *suicidal behaviors*.

Prevalence

In 2004 (the most recent year for which data were available) suicide was the third leading cause of death among youth aged 10 to 19 years old. Although suicide rates in this age group declined from the mid-1990s until 2003, the rates increased dramatically in 2004 for 10- to 14-year-old females (an increase of 76% from 2003–2004), and in 15- to 19-year-olds of both genders, with the rate for females

increasing by 32% and male by 9% in one year (Center for Disease Control, 2007). In 2004, 8.2 persons per 100,000 in the population aged 15 to 19 committed suicide (12.65 for males and 3.52 for females). There were 283 confirmed suicides among 10- to 14-year olds in that year (American Association of Suicidology [AAS], 2006). It is estimated that 170 children younger than age 10 commit suicide each year (Zametkin, Alter, & Yemini, 2001). Most experts agree that these figures are an underestimate, as some deaths recorded as accidental may actually be suicides.

Despite the recent overall decline in suicide rates among youth in general, the rate for males aged 10 to 14 actually increased from 1981 to 2001, with the largest overall increase found for Black males aged 10 to 14. The rate for this group increased 233% from 1980 to 1995 (AAS, 2006). Male youth commit suicide at a rate five times that of females (National Institute of Mental Health [NIMH], 2005), although females make more attempts and have more suicidal ideation than males. In 2003, 21% of female students reported seriously considering suicide, compared with 13% of males (National Adolescent Health Information Center [NAHIC], 2006). Data from a national sample of high school students in grades 9 through 12 (National Center for Health Statistics [NCHS], 2004) reveal interesting trends over the last decade or so. The percent of students who seriously considered suicide declined from a high of 29.0 in 1991 to 16.9 in 2003 for males, and from 37.2 to 21.3 for females. Similar reductions are evident for all grades and ethnic groups. For students who acknowledged having made a suicide attempt, however, an increase was found. In 2001, the percentages were 3.9% for males, and 10.7% for females; in 2003, those percentages were 5.4% and 11.5%, respectively. An increase is also detected in the percentage of students who made a suicide attempt requiring medical attention; males increased from 1% in 1991 to 2.4% in 2003; females increased from 2.5% to 3.2% in the same time period. Thus, although rates of completed suicide have declined, these data suggest there is no reason to be complacent.

Combining data from the U.S. Census Bureau and the NCHS, the following profile emerges. The overall U.S. population increased approximately 27% in the years from 1980 to 2002. In that same period, the number of deaths of children aged 5 to 14 years declined by 33%, suggesting considerable progress given the population increase. Declines are found in the number of accidental injuries, as well as deaths from cancer. In contrast, during this same period, the number of suicide deaths in that age group increased by 86%. For the 15- to 24-year-old age group, death from all causes declined by 33%, and the rate of suicide also decreased by 23%. It seems that there is a greater reduction in suicide among older teens and young adults than in younger children and early teens. Although the rate has declined among older teens, it lags behind the improvement seen for other causes of death.

Role of Schools

Schools are a logical context in which to address the issue of child and adolescent suicide. Most children attend school 5 days a week for 36 weeks a year, where they are in contact with trained professionals who are in a position to provide information, observe behavior, recognize an increase in stress, and build trusting relationships. Key among those professionals is the school counselor, whose specialized training and skills argue for a central role in the school's efforts to reduce suicidal behaviors among youth.

Prevention. The concepts of primary, secondary, and tertiary prevention are useful frames for the schools' role in suicide reduction (Poland, 1989). Primary prevention efforts target the general population (all students) and have as a goal increasing awareness and knowledge of suicide along with enhancing resilience in students in order to prevent suicidal ideation from emerging. Primary prevention programs are usually components of the curriculum (e.g., health) delivered by teachers or school counselors in a classroom setting. Some programs include a screening component, by which students at risk for developing suicidal behaviors are identified, either by staff or by students themselves. These students are encouraged to seek assistance in order to prevent the emergence of suicidal behaviors. One of the resources for help for students at risk is the school counselor.

Secondary prevention efforts target those who are known or believed to be at risk for developing suicidal behaviors. These students may be identified by screening procedures, referred by self or others (parents, teachers, administrators), or referred by contact from outside agencies (police, health providers). Services to these students may take the form of support groups, other counseling groups (e.g., self-esteem building), monitoring, and programs designed to address other risk factors (e.g., substance abuse) and thus may indirectly impact the risk for suicide. Even programs (such as buddy systems) for new students can be considered secondary prevention of suicide, as transitions are known stressors that increase risk for suicide in vulnerable students. These prevention efforts are often provided, initiated, and monitored by the school counselor.

Tertiary prevention involves actions directed at those who have already been affected by a suicide, including students who have made an attempt and then return to school and students who have been exposed to the suicide of a friend or family member. The goal of tertiary prevention is to reduce the level of distress and assist students in returning to their former level of functioning. This includes

monitoring for signs of increased suicidal ideation, as loss is frequently a precipitant of suicidal behavior. Again, it is the school counselor who is largely responsible for providing these services.

Intervention. The role of the school becomes one of intervention when a student has been identified as suicidal. The student is provided with support, while the counselor assesses the lethality of the student's suicidal behaviors. The specifics of this task will be discussed in greater detail in the Practice section below. At this point, it is important to note that the counselor has a responsibility to notify the parents or guardians and assist them in obtaining appropriate psychological services for the student, from outpatient counseling to hospitalization. The school counselor must also notify the school administration according to established procedures.

Postvention. One of the most difficult aspects of dealing with suicide in the school is responding to the suicide of a student. Again, details of postvention strategies will be discussed below, but it is important to recognize that there is a fine line to walk between ignoring and glamorizing a suicide while providing support to those students who are most affected. In addition, a topic that receives too little attention is that of the impact of a student suicide on the counselor who may be providing support for students, family, and teachers and whose own needs are often ignored.

Court rulings. School counselors' concerns about liability increase their stress when dealing with a possibly suicidal student. The school counselor must weigh the potential impact on the counseling relationship if confidentiality is breached against the responsibility for protecting students and taking all possible steps to prevent a suicide. Despite the prevailing view that "It is not easy for bereaved parents to hold a school board liable for their child's suicide" (Cafaro, 2000, p. 25), and the collateral belief that courts are reluctant to hold school counselors or other school personnel liable for injuries, the courts have increasingly ruled that certain acts of violence (to self or others) can be predicted, which means that school counselors could be sued on that basis (Capuzzi, 2002). Some of the influential court cases will be summarized below.

A case that signaled a willingness of courts to hear cases in which a school's liability for a student suicide is the basis of the suit was that of *Kelson v. City of Springfield, Oregon* (1985; Mathai, 2002). Although the case was settled out of court, it was the first case in which a lawsuit was allowed when the school did not intentionally harm the child. The basis of the suit was the inadequate training of district employees to respond to this situation. In this case, a 14-year-old boy killed himself with a gun he had brought to school. Administrators had seen the gun, read a suicide note written by the student, denied his request to see the school counselor, and permitted the student to go to the restroom alone, where he shot himself.

Another relevant case, particularly for school counselors, is that of *Eisel v. Board of Education of Montgomery County, Maryland* (1991; Pate, 1992). This case was significant in that the highest state court overturned the rulings of lower courts, which had held that school counselors were immune from liability for the suicide of a student. Earlier rulings had released school counselors from liability unless the counselor had "physical responsibility for the client" (p. 16). In this case, the friends of a 13-year-old student told their school counselor that a friend of theirs told them she intended to commit suicide. The friends' counselor told the student's counselor, who discussed it with the student. The student denied that she had made the reported statements. The counselor took no further action, and the student later died in a murder–suicide pact with another girl. The victim's father sued, saying that the counselor should have notified him in order to prevent the suicide. The case was returned to lower courts to determine whether the counselors in the case had information and whether the suicide was related to their failure to contact her parent, but the appeals court was clear that school counselors have a duty to prevent the suicide of a student when they are aware of the danger. The ruling, which stated that "school counselors have a duty to use reasonable means to prevent a suicide when they are on notice of a child or adolescent student's suicidal threat" (*Eisel v. Board of Education of Montgomery County, 1991*, as cited in Milsom, 2002, p. 456), should be the basis of school counselors' decision making in these situations. Note that notifying a parent is often the "reasonable means."

These cases stress that school counselors should take any threat of suicide seriously, and that they are expected to respond in a way that demonstrates they are exercising the same degree of care as would other school counselors of similar education and experience (Hermann, 2002).

Training of School Counselors for the Role in School Suicide Prevention, Intervention, and Postvention

Specific training for the school counselors' role in dealing with suicide is lacking in most graduate training programs (Foster & McAdams, 1999). Council for Accreditation of Counseling and Related Educational Programs (CACREP) guidelines do not require training for suicide response, and most programs, even those not accredited by that organization, follow CACREP guidelines in designing their curricula. If an elective course in crisis intervention or suicide

is available, not all students will have that training. Thus, most school counselors rely on general counseling skills and techniques, and professional training workshops and other sources, for their skill development.

A national survey of 186 high school counselors revealed that only 57% had received information about suicide from college classes. Professional workshops and conferences on suicide were the source of information for 84% of respondents, with on-the-job training (66%) and in-service programs (40%) also utilized (King, Price, Telljohann, & Wahl, 2000). Mathai (2002) found that only 68% of her sample of 517 school counselors believed they were adequately prepared to respond to a crisis involving suicide; 93% and 81% reported feeling prepared to deal with suicidal ideation and suicidal gestures, respectively. She observed that more school counselors in the sample said they were prepared than said they had had training in responding to a crisis involving suicide, and concluded that experience must be an important factor in school counselors' self-efficacy in responding to a suicidal crisis.

Several studies investigated the knowledge and confidence of high school counselors regarding working with suicidal students. King et al. (2000) found that the majority of counselors were knowledgeable about the risk factors for adolescent suicide, and most knew the appropriate steps to take if a student was suicidal. Most also knew what should be done in the event of a suicide (postvention strategies). Results also indicated, however, that only 38% of their sample of high school counselors believed they could recognize a student at risk for suicide. This finding is a concern, as knowing what to do if a student threatens suicide is useful, but if the counselor is unable to identify students at risk, he or she may not have the opportunity to intervene. It is important to note that this study utilized a questionnaire, and one cannot predict actual behavior from the responses.

By comparison, King and Smith (2000) reported that of the school counselors in Dallas, Texas, who participated in the SOAR (Suicide Options, Awareness, and Relief) training provided by the district, 56% indicated they believed they could identify a student at risk for suicide. This finding suggests that training is helpful in increasing counselors' confidence and self-efficacy regarding suicide intervention. Counselor educators must recognize the frequency with which school counselors deal with all aspects of suicide, and they must ensure that their graduate programs prepare them for this role. Commenting on the lack of suicide training in graduate psychology programs, Dexter-Mazza (2004) noted, "Overall, graduate programs need to do a better job of providing formal training to students in working with suicidal clients. Students should be provided with opportunities to receive formal training through special topic courses, lectures, workshops, and practicum experiences" (¶ 7). This recommendation seems appropriate for graduate programs in school counseling as well.

Theory

There is no single widely accepted theory of suicidal behavior. In fact, theory development has been overlooked in the field of suicidology (Laux, 2002; Rogers, 2001; Westefeld et al., 2000). Several theories have been proposed and will briefly be described below (see Laux; Westefeld et al., 2000).

The Overlap Model developed by Blumenthal and Kupfer (1986) proposed five areas or domains that influence suicidal behaviors. These domains are (1) the psychosocial milieu (which includes social support), (2) biological vulnerability (including early development), (3) psychiatric disorders, (4) personality factors (including aggression and impulsivity), and (5) family history and genetics. Each domain is conceived of as a circle, with portions of the circles overlapping. The greater the area of overlap of the five circles, the higher the risk for suicide.

Jacobs, Brewer, and Klein-Benham (1999) suggested a three-element model, which includes (1) predisposing factors, (2) potentiating factors, and (3) a suicide threshold. In this model, predisposing factors are mental disorders, substance abuse, and schizophrenia. Potentiating factors are family history, the social context, personality disorders, stressors, and access to firearms or other lethal means. The combination of these factors impels a person toward the suicidal threshold and suicidal behavior.

The Suicide Trajectory model was proposed by Stillion, McDowell, and May (1989, as cited in Stillion & McDowell, 1996) and is based on the premise that a combination of biological, cognitive, psychological, and environmental risk factors interact to bring the individual to consider suicide (suicidal ideation). Suicidal ideation begins when the combined pressure from the four risk factors overtaxes the individual's coping skills. Once suicidal ideation has occurred, if a triggering event ("last straw") is added to the mix, the individual engages in suicidal behavior.

The Cubic model (Shneidman, 1987) is composed of 125 cubelets which together form a cube with three planes: (1) press, (2) pain, and (3) perturbation. *Press* involves things that happen to a person, both positive and negative, with more negative presses (e.g., humiliation, failure, and rejection) moving the person closer to suicide. In the model, the opposite sides of the plane are positive and negative. It is not the events that create the press, but the individual's interpretation of those events that is critical. *Pain* results from unmet psychological needs. Those needs include autonomy, achievement, recognition, nurture, and avoidance of shame and humiliation. The third

plane, *perturbation*, refers to the condition of being upset, which can lead to black and white thinking and tunnel vision (constriction). This plane ranges from low to high. The three planes can be rated from 1 to 5, with 5 being the greatest intensity. With three ratings of 5, an individual is at maximum risk for suicide because the individual is experiencing maximum pain, press, and perturbation. Shneidman expressed the belief that intolerable pain is the central feature of suicide and that all other risk factors are only important in the ways they cause current pain. He also suggested that the model provides keys to treatment: "(a) reduce the hurt, (b) lift the blinders, (c) pull back from action, and (d) lighten the pressure, even just a little bit" (p. 177).

A comprehensive theory of suicide developed by Rogers (2001) was based on both existential principles and constructivist theory. He proposed that humans attach meaning to the world and the people who populate it. The meaning is created in a social context and is in some ways constrained by the environment. In this theory, environmental challenges (triggering events) cause the individual to consider response options, which, according to Rogers, consist of altering constructions (*accommodation*), keeping constructions (*assimilation*), or suicide. The school counselor might find this theory useful when there is an identifiable precipitating event. For example, if the triggering event is a loss of a relationship, the underlying construction might be "Important relationships must last forever," or "If he or she stops loving me, I am not worthy of being loved" (p. 23). The counselor might then assist the student in revising the underlying constructions, helping them be less rigid (modifying "must," "always," and "never" ideas) or reframing the event, so the loss is viewed as an opportunity for learning. Rogers considered these interventions to be short-term crisis response strategies, which is the kind of intervention the school counselor might make. The student would be referred to outside resources, who would help the student examine the various influences that contributed to the maladaptive constructions, with a potential outcome of revising the constructions so that they are more flexible.

Although none of these theories is widely accepted, each has something to contribute, and the school counselor's thinking about suicide might be clarified using a theoretical model. Research related to suicide is the topic of the next section.

Research

Much of the research in suicide has been devoted to identifying risk and protective factors for suicidal behaviors. A knowledge of risk factors allows the school counselor to be more vigilant with vulnerable youth. In this section, we will briefly review research on risk and protective factors, and then summarize the research related to depression in children and adolescents, which has been strongly linked to suicidal behavior. Then we will examine the available research on the efficacy of suicide prevention programs in schools. We will consider the impact of this information on the counselor's ability to predict suicidal behavior. Finally, we will discuss the methodological concerns with research in this field. First, however, we will review aspects of development that help explain suicidal behavior in children and adolescents, as these factors (which can be both risk and protective factors) are necessary to understand this population.

In addition to the known risk factors, what do we know about children that might explain suicidal behavior in youth? In younger children, a lack of cognitive maturity may allow them to maintain a belief that death is temporary or that death is a pleasant state (Pfeffer, 1997). They may believe that their death will reunite divorced parents, or that they will be the constant preoccupation in the thoughts of others once they are dead. Other misunderstandings, such as the belief that they will have a reunion with dead family members or the fantasy that they will watch others grieve over their death, may impel some children to this extreme behavior (Stefanowski-Harding, 1990). Some may have a heightened experience of hopelessness under stress because of their cognitive immaturity and inability to think abstractly and hypothetically.

Prepubertal children think concretely, often in black and white dichotomies, which make it difficult for them to generate multiple solutions to a problem. Young children are not able to estimate the lethality of a method or to envision the outcomes of their behavior (Pfeffer, 1997). The good news is that their ability to plan and carry out a suicidal plan is also limited by their immaturity (Goldman & Beardslee, 1999).

Some risk factors, such as depression, are difficult to detect in children, as symptoms manifest differently in children than in adults. (Bauman, 2004). This is also true for adolescents, who may mask depression with a variety of behaviors such as promiscuous sexual activity, acting out or delinquency, substance abuse, eating disorders, and even physical symptoms. Some have theorized that adolescent substance abuse often begins as an attempt to ameliorate depressive symptoms (Allberg & Chu, 1990). Other characteristics of adolescent thinking, originally described by Elkind (1967), are the imaginary audience or adolescent egocentrism, and the personal fable of invincibility. Adolescent egocentrism influences suicidal thinking in several ways: Adolescents have a sense that others are watching them closely and notice any deviation from perfection, which magnifies any perceived flaw or mistake, thereby increas-

ing the level of distress. In addition, they may also believe that their death will have a momentous impact on others, that those who have wronged them will be overwhelmed with guilt and shock, and that their death will show the world how badly they have been treated. Although most adolescents have the cognitive understanding of the finality of death, they may "forget" this in their preoccupation with romanticized notions of the impact of their death on others. Their need to communicate or make a statement to the world predominates, and the finality of death is relegated to a minor role in their thinking (Allberg & Chu, 1990).

Many adolescents who engage in suicidal behavior have experienced a significant loss and may come from families in which mental illness, addictions, and other unhealthy environmental elements are common. These children and adolescents lack models for effective coping skills and are unequipped to deal with stresses in their own lives. Further, they may not be able to communicate their pain to adults in the family and by generalization to any adult, and so they experience acute isolation and a sense of helplessness and hopelessness. Such conditions are the breeding grounds for suicidal thinking. Even in families with a more positive environment, adolescents are in the process of separating from parents and establishing their own identities, which may deprive them of parental support at a time when it would be most needed. They are more likely to confide in peers than in adults, and adolescents may not have the skills to respond to a suicidal friend.

Any discussion of risk and protective factors for youth suicide must begin with a caveat. The presence of a single risk factor is not evidence of suicidal tendencies, with one exception: A previous attempt is a major risk factor (Zametkin et al., 2005). In fact, many individuals, both youth and adult, possess multiple risk factors and never contemplate suicide. Haley (2004) categorized risk factors into two categories: (1) *predisposing factors*, which are those underlying, more chronic and enduring factors, and (2) *potentiating factors*, which are the immediate situational influences on a suicidal event. Moscicki (1995, as cited in McKeown et al., 1998) used the terms *distal factors* (mental disorders, genetics, and family factors) and *proximal* (situational factors and stressors) to distinguish the two categories. It is widely accepted that predisposing distal factors combine with proximal factors in a social context to increase the risk for suicidal behavior (McKeown et al., 1998). Here we focus mainly on proximal factors.

Proximal Factors

McKeown and his colleagues (1998) have cautioned that focusing on stressors may cause one to overlook the important influences of mental disorders and family factors in suicidal behavior in adolescents. That is, while stressors might be the immediate factor, they are unlikely to impel a youth to suicide without the presence of the other underlying factors.

Stressful life events contribute to the risk for suicide in youth. In younger children and adolescents, conflict with parents is associated with increased risk for suicidal behavior, while for older adolescents, romantic problems and breakups are seen more often. The loss of an important relationship is a factor in up to 70% of suicide attempts or completions (Jacobs, 1999). It is likely that in children and adolescents whose suicidal behavior is precipitated by an actual or perceived loss, there were other risk factors present prior to the stressor. Children may not have the cognitive maturity to generate alternative solutions to problems, and if they also lack coping skills and the support of a caring adult, suicide may appear to be the only choice.

Kirk (1993) grouped adolescent stressors into two different groups: (1) those that are *expected and normative* (such as puberty, physical changes, school changes, and/or cognitive changes) and (2) those that are *unexpected* or *extreme* stressors (such as physical illnesses; developmental delays; parental separation, divorce, or death; death of a friend; abuse; legal difficulties, and/or sexual problems). A nationwide Gallup Organization (1994) survey was conducted in 1991 and was then repeated three years later. Of those participants who came close to or actually made an attempt, the most often cited stressor preceding an attempt was family problems, followed by depression, low self-esteem, peer problems, life in general, and school problems.

Kalafat (1990) distinguished between *causes* (risk factors) and *precipitants,* events that occur in an at-risk student's life that may push that student to make an attempt. He observed that it is not simply being in trouble (with school or police) that is the precipitant, but uncertainty and intense fear of what might happen increase the danger. Disappointment and rejection (however minor they may seem to someone else) may also be the impetus. I recall a suicide that shocked a community because the high school senior seemed to "have it all." He was a top student, an athlete, from an affluent family, and so forth. Although he had received several attractive offers from colleges, when he was rejected by the prestigious institution that was his first choice, he shot himself. Anxiety over impending change (again, however small to an outsider) can become so intense that the youth becomes desperate. A change in schools, or even in classes, as well as major changes in family constellations, can trigger some youth to suicide. If a vulnerable youth has experienced the death of someone important, the anniversary of that loss might revive the sadness and impel the youth to make an attempt.

In addition to evidence for risk factors, several protective factors have been identified. Using data from a sample of 13,110 students in grades 7 through 12, Borowsky, Ire-

land, and Resnick (2001) found that for all subjects, perceived strong relationships with parents and family reduced the risk for suicide. For females, an additional protective factor was emotional well-being, while for boys, grade point average served as a protective factor. Data indicated that for some males, high parental expectations for school achievement, more people residing in the household, and religiosity were protective; while for girls, counseling services at school and parental presence at home at important times in the day were protective. Interestingly, these findings for girls or boys did not apply to the opposite gender. Further analysis showed that for females with all identified risk factors, including a previous attempt and few protective factors, the probability of a suicide attempt in the time period between two interviews (interval averaged 11 months) was 36%. For African Americans with no risk factors and high levels of protective factors, the probability was 0.2%. Most important, for all racial/ethnic groups and both genders, the presence of three of the protective factors reduced the probability of an attempt by 70% to 85%. Family closeness and religiosity were also found to be protective in Latino adolescents (O'Donnell, Stueve, Wardlaw, & O'Donnell, 2003). Social support is a protective factor, in contrast to social isolation, which elevates risk for suicide (Rutter, 2004).

Prevention Programs

The absence of solid research evaluating the effectiveness of suicide prevention programs has been noted by researchers (e.g., Aseltine & DeMartino, 2004; Breton, Tousignant, Bergeron, & Berthiaume, 2002; Eggert, Thompson, Randell, & Pike, 2002). Although many schools have formal suicide prevention programs, less than 40% of a sample of high school counselors agreed that their school or district had a written policy specifying how a prevention and intervention program is evaluated (Malley, Kush, & Bogo, 1996). A review of school-based suicide prevention programs with suicide or suicide attempts as outcome measures was conducted in 2001 by the Harborview Injury Prevention and Research Center (HIPRC) at the University of Washington. Based on six studies published between 1997 and 2000, the reviewers concluded that there was only weak evidence for the effectiveness of such programs, but there was also no evidence that the programs resulted in an increase of attempts or suicide associated with the programs.

A more recent review (Doan, Roggenbaum, & Lazear, 2003) examined several school-based programs, including evaluation information. Most of these evaluations used outcome measures other than suicide attempts or suicide. HIPRC (n.d.) noted that there is insufficient empirical evidence that other outcome measures other than attempts or suicides correlate with suicide risk. Nevertheless, a brief overview of 10 of these programs will be included here, based on the Doan et al. review, unless other sources are cited.

BRIDGES is a program designed to increase skills of school personnel, including school counselors. Participants learn assessment and intervention skills to use with students, families, and peers and are assisted in developing school policies and procedures for dealing with all aspects of suicide. Evaluation information was not available at the time this chapter was written.

Project C-CARE is an individualized assessment interview, using a computer-assisted program (Measure of Adolescent Potential for Suicide) followed by a brief counseling session and contact with the parents. Extensive evaluation studies have been conducted on this approach.

Project CAST is often used with the C-CARE program when the student is found to be at risk for suicidal behavior. The program begins 4 weeks after the C-CARE component, and utilizes a 12-session structured group program at the student's school over a 6-week period. Research using randomized experimental design compared effects of C-CARE, C-CARE plus CAST, and treatment "as usual" with 341 potential school dropouts who were identified as at risk for suicidal behaviors (Eggert et al., 2002; Randell, Eggert, & Pike, 2001). As expected, participants in all three conditions demonstrated reductions in suicidal behaviors, depression, and drug involvement, but the reduction in depression was greater for the two experimental conditions than for the usual care group. In addition, the CAST program participants evidenced greater reductions in problem alcohol and drug involvement compared with the other two conditions. C-CARE plus CAST students demonstrated increases in other factors considered to have an impact on suicidal behaviors: personal control, problem solving, coping skills, and perceived family support. Both C-CARE and C-CARE plus CAST students showed decreased depression and enhanced self-esteem, and met family goals. Note that in all cases, the effects were measured at the end of the CAST program for all three groups; follow-up data were not reported. The same research team, however, also examined the program's effects on 460 at-risk youth and included a 9-month follow-up assessment. Results showed a faster rate of decline in attitude toward suicide and suicidal ideation in the two treatment groups compared with the control group, and the reductions in suicidal behaviors were maintained at a 9-month follow-up. The two treatment conditions also showed long-term decreases in depression and hopelessness, and CAST showed increases in personal control and problem-solving abilities (Thompson, Eggert, Randell, & Pike, 2001). Overall, research has provided promising empirical evidence of the possible effectiveness of the program.

Signs of Suicide (SOS) resulted in an increase in the number of youth seeking counseling for themselves or friends following the program (Aseltine & DeMartino, 2004). This program has been selected by the Substance Abuse and Mental Health Services Administration (SAMHSA; 2007) as a Promising Program, which means it has been deemed to have demonstrated positive outcomes, but has not yet provided evidence of consistent positive outcomes in carefully controlled research designs. The program utilizes a video and discussion guide that are covered in one to three class periods, as well as a depression screening instrument (the Columbia Depression Scale). The students are taught the elements of the acronym ACT: *acknowledge* the signs of suicide in peers, let the person know you *care* about them, and *tell* a responsible adult. An experimental design using random assignment to treatment and control conditions was used to evaluate the program by posttest only. Students in the treatment group self-reported significantly 40% fewer suicide attempts than the control group. The impact of the program on student help-seeking, however, was not significant nor was level of suicidal ideation. Despite some limitations, this research was important in that it evaluated a school-based program using a randomized experimental design (Aseltine & DeMartino).

Miami-Dade County Department of Crisis Management Prevention Program was established in 1987 to assist staff in schools (and community agencies) in identifying, assisting, and referring at-risk students by training "crisis care core teams" in each school. The program includes a hotline to provide assistance to staff, and a curriculum component for K–12; the topic of suicide is not directly addressed until the 10th grade component. Data indicate that the program did not decrease reported suicidal ideation, but did decrease suicide attempts and completions. Note that there was no comparison group reported, and participants were not randomly assigned to treatment.

Services for Teens at Risk (STAR) offers three programs directed at school personnel. In the first program, teachers and other school staff are taught to recognize risk factors and make appropriate referrals. The next level provides training in evaluation of risk and working with families and providers of mental health services as well as students. The third level trains school personnel to deliver the first level training in their setting. No evaluation data were available.

The Columbia TeenScreen Program conducts screening and assessment for depression and other disorders that put a youth at risk for suicide. The program makes available a computerized interview to those who are identified in a paper-and-pencil screen as in need of the more in-depth interview. An evaluation conducted in 1996 found that the process identified many teens at risk for suicide whose risk was not known prior to the screening. Their Web site (http://www.teenscreen.org/) indicates the program is used in 40 states. Although program implementation may vary among sites, precluding overall evaluation, research was conducted to determine whether asking about suicide (as in a screening or follow-up interview) caused distress or increased suicidal behavior (Gould et al., 2005). The randomized controlled study with 2,342 high school students found no evidence that the suicide screening increased either distress or suicidal behaviors.

Dallas school counselors were involved in a program to train all counselors in the district on interviewing and assessment techniques for use with students who threaten suicide. An evaluation of Project SOAR (Suicide, Options, Awareness, and Relief) observed that efficacy for suicide intervention was higher in the school counselor group receiving the SOAR training than in those who did not. The overall rate of those who strongly believed they could identify a potentially suicidal student, however, was only 56% (King & Smith, 2000). This speaks to the importance of school counselors' need for information, training, and supervision in working with suicide prevention, intervention, and postvention.

A curriculum program was developed and delivered to Zuni (American Indian) adolescents attending their local high school. Researchers developed a life skills program (treatment condition) that was delivered by two nonnative teachers paired with two Zuni cultural resource persons; one nonnative teacher provided the usual curriculum, which was the no-intervention condition. A life skills curriculum was chosen because it was thought to be effective in reducing cognitive and behavioral risk factors for suicide and to be culturally appropriate for the population. Three methods were used in an attempt to measure the effectiveness of the program, and results were equivocal. The researchers concluded, however, that there were statistically significant positive effects from the program (LaFromboise & Howard-Pitney, 1995).

A multilevel program that includes a program for educators, parents, and students is ASAP (Adolescent Suicide Awareness Program; Kalafat & Ryerson, 1999). Program developers were concerned that programs were not maintained after initial implementation efforts, and they surveyed schools in which the program had been implemented to assess how well the program had been institutionalized. Over time, many schools dropped the ongoing educator and parent training, but most retained the student training, although for less time that the original 6-hour format. As 33 of 46 public high schools in the county had received the training, suicide rates for 15 to 24 year olds were examined for three 5-year periods (preimplementation, implementation, and postimplementation). While rates for that county were lower than those of the state and nation at all three time periods, the drop postimplementation was quite large. The authors acknowledged that this decline

cannot be attributed to the program, but also noted that the decline in a county so heavily saturated with suicide prevention programming gives support to the notion that talking about suicide does not increase suicide rates. They do not provide data regarding attempts or ideation for comparison.

For school counselors interested in implementing a suicide prevention and intervention program, there are clearly a number of models from which to choose. They vary in the degree of empirical support for effectiveness, and also in target populations (staff, parents, students, community resources) and in other components, so that counselors can determine the best fit for their environments—and they do not have to reinvent the wheel!

Prediction of Suicide

Unfortunately, the accuracy with which counselors and mental health professionals are able to predict suicide on an individual basis is quite poor (Goldney, 2000; Overholser & Spirito, 2003). Because suicide has a low base rate (is fairly rare), and because the risk factors are not specific (i.e., many with the risk factors do not commit suicide), prediction on an individual basis is an educated guess. Pokorny (1983) concluded that it was not feasible to identify specific individuals who will commit suicide. Goldney (1990) conducted a follow-up to the Pokorny study (1983) and reported similar findings, saying that our ability to "predict suicide is very limited" (p. 50). Muzina (2004) observed that despite all that is known about risk factors for suicide, "it is very difficult to predict whether an individual patient will attempt it" (p. 244). This suggests that school counselors, as others who encounter suicidal individuals, are far from infallible and, thus, need to accept their limitations. Despite all the best efforts of the most skilled and concerned school counselor, it is possible that some students will commit suicide. How such events affect the counselor is the subject of the next section.

Effect on the Counselor of a Completed Suicide

Much of the literature related to the impact of client suicide has been done with psychiatrists or interns in clinical settings. No study of the impact on school counselors was located. Many of the dynamics, however, are comparable, and the lessons from the research have important implications.

Ruben (1990) identified two types of reactions in clinicians who had experienced the suicide of a client. The first is the grief response, which was similar to that of anyone experiencing the loss of an important person. Those reactions include guilt, anger, denial, and repression. In addition, there are clinician-specific reactions, such as self-blame, a sense of inadequacy, and responsibility for the death. The clinician's grief response is complicated by the need to respond to family members, colleagues, supervisors, and others. In the case of the school counselor, this includes having to be of assistance to students. At times, the family may seek to assuage their own guilt by blaming others, which intensifies any guilt the counselor may already feel.

Gorkin (1985) proposed two factors that affect the clinician's ability to deal with a suicide. First, the greater the level of omnipotence (the belief that the clinician should be able to do everything for a client or student) the more difficult the impact of the loss might be. The second factor is the nature of the relationship to the deceased client. If the relationship included hostility (expressed or unexpressed), the grief process will be more difficult. Gorkin's signs of "pathological mourning" include the following: excessive feelings of guilt, expectations of harsh judgment from colleagues and supervisors, obsessing about one's ability to continue to do the job, and doubts about the value of counseling or therapy. When these factors are present, it is difficult for school counselors to be effective in their work, as they may avoid the mention of suicide or working with student at risk for suicide, or they may become overly careful and reactive when the subject comes up.

Other researchers cited by Ruben (1990) found young or less experienced therapists felt desolated by the lack of support from peers. He recommended that when a counselor learns of a suicide of a client, the counselor should gather as much unbiased, accurate information as possible before talking with others. Counselors should seek trusted colleagues and supervisor for support and should recognize that some symptoms, such as nightmares, are common. Depending on how severe the symptoms are, Ruben has advised counselors to seek professional help. This advice certainly applies to school counselors.

Several other studies could be reported here, but results are similar to those already discussed. It is important to consider the case of a school counselor who experiences the loss of a student. I have unfortunately had that experience and can attest to the accuracy of the research findings. An added difficulty for a school counselor, as opposed to a counselor in another setting, is the isolation from colleagues who can provide support (and hopefully, relieve the grieving counselor of some duties in the immediate aftermath). Some high schools have large counseling departments, but small or rural schools may not. In addition, principals and other administrators may not be prepared to deal with suicide and may in their own shock and grief be unable or unwilling to provide needed support. The presence of district crisis response teams can be a lifeline for the counselor in this situation. In my case, they were available, responsive, supportive, and helpful. Had

they not been, it is likely that the experience would have been far more devastating. Speaking to school counselors who were actively involved in postvention after the suicide of a student, Stefanowski-Harding (1990) said, "If you do not talk to a crisis team, talk to someone—other staff people, other counselors, friends, or mental health professionals. Be sure to nurture yourself the way you nurture your clients" (p. 335).

Practice

In this section, we will discuss the elements of good prevention programs, review available assessment instruments that are appropriate for children and adolescents, discuss intervention and referral practices, and review important components of an effective postvention response. Then we will examine the needs of elementary and secondary school counselors, and reflect on pertinent ethical issues. We will end this section with a discussion of issues related to diversity.

Prevention Programs

Because specific prevention programs were reviewed early in this chapter, the focus here will be to identify elements that have been found to be important for implementation in schools; however, experts do not agree on which components of a suicide prevention program are necessary or helpful. For example, while most experts support training of staff, suicide awareness in the student curriculum is still quite controversial. In their training materials, the Center for Mental Health in the Schools (CMHS; 2002) urged caution in using an education component with students. They have based their concern on the scant research findings which indicate that while students do gain some *knowledge* about suicide, they do not change *attitudes* towards suicide or help-seeking *behaviors* after such education. Further, they point out that at least one study found harmful effects on students who had made a prior suicide attempt.

Garland and Zigler (1993) are concerned that some curricula, in an effort to destigmatize suicide, avoid mentioning the link to mental illness. The intent is to make help-seeking for suicidal thinking or behaviors more acceptable to youth who may have a negative perception of mental illness. Doing so, however, may indirectly suggest that suicide is a normal (if extreme) response to stress, a view that can easily be misinterpreted by vulnerable youth. Some programs may utilize popular media, which tend to glamorize suicide and send the wrong message to those at risk. Kalafat (1990) has also advised against using media that depict a suicide. Another concern is that because many students at risk are not actually attending school (runaways, dropouts, incarcerated youth, and truants), the message may not reach the target population (Garland & Zigler).

Others (Kalafat, 1990; Poland, 1989) believe that students already know about suicide and that accurate information is important. They encourage educators to incorporate suicide awareness into the curriculum, but advise careful planning and scrutiny of that curriculum. One recent approach that merits such scrutiny is outlined by J. S. Wodarski, L. A. Wodarski, and Dulmus (2003) in their book, which serves as a manual for the educator. The curriculum is a student team–based approach because the authors believe that students increase self-esteem and develop positive peer relationships in such a format. There are both adolescent and parent components: Adolescents focus on education, skill development, and problem solving, while parents receive the same information that the students do, along with communication techniques designed to strengthen the parent–child relationship. The student curriculum is a 6-week course, using 50 minutes per day. The parent program is delivered to parent groups in six 2-hour weekly sessions. No evaluation of the program is provided.

School counselors who are considering how best to prevent suicide in their schools might ponder this statement from the Center for Disease Control: "Many suicide researchers believe that broad-based primary prevention programs focusing on health enhancement may be of greater value than programs that address only suicide" (MHS, 2002, p. 24). Note that in the description of prevention programs earlier in this chapter, several programs do take the broader approach to educating students. Dyck (1991) reviewed the obstacles to implementing suicide prevention in schools, and the eager school counselor might refer to his chapter before moving forward.

Kalafat (1990) and Poland (1989) stress the importance of effective and frequent training for all staff. As cafeteria workers, custodians, bus drivers, and so forth all interact with children and may have different perspectives for observing them, they should all be included in the training. A single training, delivered in one or two hours, can provide adequate background for staff. In addition to providing information and statistics about youth suicide, staff should receive information on specific procedures for identifying and referring potentially suicidal students. Garland and Zigler (1993) contend that educating school counselors, teachers, and other staff does not involve the danger that curriculum-based programs have for imitation effects on adolescents. Parent training is also recommended by many experts, and several developed programs have a parent component as part of the package.

Screening and Assessment

Whether large-scale screening should be conducted in schools is also open to debate. There is no doubt, however, that school counselors are the school professionals who will have responsibility to assess risk for suicide (Davis & Sandoval, 1991; Poland, 1989; Stefanowski-Harding, 1990). In this section, we will discuss some principles related to suicide assessment, review available assessment tools the school counselor may wish to use, and also provide some informal, widely used assessment techniques.

Before discussing the specifics of assessment, we should point out the importance of basic clinical communication skills. Talking about suicide is not everyday conversation, and approaching an adolescent on this topic requires sensitivity and empathy. Further, the counselor needs to be firm in conveying that suicide is not an acceptable option. The school counselor should appear comfortable discussing death and suicide, genuinely concerned about the student, and competent to make appropriate decisions and take necessary action. Some counselors choose to tell students that they have helped many suicidal students and that they will help the present student as well.

The school counselor must also wrestle with the issue of trust and confidentiality. In the current climate, it is wise to notify parents when there are any concerns about suicide, but counselors may fear that they will lose the student's trust by doing so. First, school counselors should always make sure all students are informed about the limits of confidentiality by explaining those limits clearly and often. Many school counselors have posters in their offices with that information. Second, if the counselor explains to the student why the contact must be made, students are less likely to feel betrayed. In many cases, the counselor may offer to have the student and counselor tell the parents together. This is where sensitivity and clear communication are essential.

In addition to suicide risk factors we have discussed, there are also danger signals that should alert school counselors that a complete assessment should be conducted. Kirk (1993) pointed out that students may not communicate suicidal thinking or behaviors directly, but reading between the lines can help the skilled counselor identify clues. Seemingly, vague statements such as, "I'm sick of everything" or "I wish I had never been born" should be considered as communication of possible suicidal thinking and should be explored with the student. Some students will reveal their feelings or fantasies about death in poems, writing, and art, which also need to be taken as signals worthy of attention. The giving away of possessions is a very clear and loud signal that suicide is a real possibility, and the counselor must intervene if that information is known. The same is true for funeral arrangements (or invitations) that are sometimes discounted. These signals are messages that must not be ignored. This is a time for more in-depth assessment of suicide risk

I will describe in some detail several widely used assessment approaches. Each uses an acronym to help the clinician remember to inquire about all pertinent issues.

The SLAP method is used when the counselor learns of a client's suicidal ideation:

> S = How SPECIFIC is the plan? Has the client thought about details? Does the client have a time frame? Has the client made special arrangements to make sure the plan will work? A client whose plan is more specific is at higher risk. For example, a client who says, "I'm going to take some pills" is at lower risk than one who says, "I'm going to pick up a refill on my prescription for Valium and take them all with a stiff Bloody Mary."
>
> L = How LETHAL is the plan? Firearms are the most lethal, along with jumping from high places or jumping in front of moving cars. Hanging, overdose, and cutting can also be lethal, but can more easily be reversed if the person has second thoughts, and they are also more easily interrupted by others. The more lethal the plan, the higher the risk.
>
> A = How AVAILABLE is the method? If the client intends to shoot himself in the head, does he have a gun, or does he plan to go to a store and buy one? Does the client who intends to overdose on barbiturates already have them, or will she have to make an appointment and request a prescription? Does the client who intends to use a knife have a knife selected? The more available the means, the higher the risk.
>
> P = Are others in close PROXIMITY? Are there significant others who could interrupt or interfere with the plan? Are there others whose help can be enlisted (e.g., to remove firearms from the home, flush medication, remain with the client)? The greater the distance and isolation of the client, the higher the risk.

One potent risk factor for suicide is a previous attempt. When the clinician learns that there has been such an attempt, the DIRT method is a useful tool to assess the seriousness of that attempt:

D = How DANGEROUS was the attempt, or how lethal was the method used?

I = What was the client's IMPRESSION of the lethality? In this case, the clinician wants to know how lethal the client believed the method to be. For example, taking ten Tylenol may not be highly lethal from a medical perspective, but if the client *believed* he would die, that is more important in assessing the seriousness of the attempt.

R = What was the probability of RESCUE? Did the client take pills when others were at home? Did the client expect a friend to arrive? Did client announce his plan to others? Did she or he choose a public place (e.g., a school restroom) where she was likely to be observed and stopped?

T = What was the TIME frame of the most recent suicide attempt? The more recent the attempt, the higher the current risk.

Poland (1989) mentioned a system known as SAL for determining the lethality of a student with a plan to commit suicide. This is a mnemonic for gathering information about the *specificity* of the plan, the *availability* of the method, and the *lethality* of the method.

Another scale that utilizes an acronym as a mnemonic device for clinicians is the SAD PERSONS scale (Patterson, Dohn, Bird, & Patterson, 1983). This scale has been adapted for use with children and adolescents (Juhnke, 1996); its modified version is called the Adapted Sad Persons Scale (A-SPS). Goldston (2003) noted that there is no research providing data on reliability of validity of this measure, but there are few measures with such data. Reliability and validity of suicide assessments are problematic for ethical reasons. No researcher would choose not to intervene in the case of a client assessed at high risk for suicide in order to test the validity of the scale.

This scale is more formal in that there are guidelines for interpretation. The scale has demonstrated usefulness in accurately evaluating suicide risk. This method is easily learned and used, and is a systematic approach that the school counselor can use in a crisis situation. The scale and interpretation for the child/adolescent version is described in the box below. Note that for sex, score 10 for males and 0 for females.

Scoring is 0 (absence of risk factor) to 10 (significant manifestation of risk)

S = Sex	Score if the person is male
A = Age	Score if the person is over 15
D = Depression	Score if there are signs of depression
P = Previous attempt	Score if there was a previous suicide attempt
E = Ethanol (Alcohol)	Score if there are symptoms of substance abuse
R = Rational thinking loss	Score if person is psychotic, disoriented, has bizarre thoughts, is confused, is irrational, etc.
S = Social support loss	Score if person has no close friends
O = Organized plan	Score if the person has a fairly detailed plan that is lethal
N = Negligent parenting	Score if person has had negligent parents, family stressors, or suicidal modeling by parents or siblings
S = School problems	Score if there are aggressive behaviors at school or deterioration in academic performance, or if there is an embarrassing or humiliating experience

Recommended intervention:

0–29	Encourage counseling services; counselor should follow-up; provide emergency 24-hour numbers (e.g., hotline).
30–49	Strongly recommend counseling and follow-up services, contact parent or guardian, get "no suicide" contract
50–69	Have formal evaluation for hospitalization unless follow-up arrangements and counseling plan are highly reliable
70 +	Arrange for immediate hospitalization

Juhnke (1996) provided some very useful additional information. He recommended that all students, even those in the lowest risk category, receive a card so that if there is a change in suicidal status, they have phone numbers at hand. He suggests putting emergency contact information on a business card and taping a quarter to it so the student can make a phone call. In the current era of cell phones, the quarter may not be necessary. It might be helpful to have emergency information printed on the reverse side of the school counselor's business card. There might also be a place to indicate a follow-up appointment. Juhnke also recommended that a student's parents be contacted if the score is above 30, but it is advisable to do so in almost

all cases. If an outside evaluation is needed, and parents refuse, Juhnke has advised that the counselor contact the local child protective service agency.

Another useful tool is the Suicidal Tendencies Scale (Crocitto, 1990) a quick initial assessment tool easily used in the school setting. No psychometric data are presented, but is easy for the school counselor to learn and apply.

Many formal assessments are available to the counselor (see Goldston, 2003, for a thorough review of every instrument available for children and adolescents as of the publication date). The most widely used assessments in schools for screening purposes are the Suicide Ideation Questionnaire (SIQ; Reynolds, 1987) and the Suicide Probability Scale (SPS; Cull & Gill, 1988). The SIQ has forms for both high school and grades 7–9. It is available only in English, and it does not ask about suicide attempts. Given that previous attempts are a high risk factor, that information is essential in identifying high-risk students. That information may not always be forthcoming from students or parents, so obtaining that information is essential to good assessment (Kirk, 1993). The SPS was designed for use with adolescents over age 13 and contains 36 statements to which students indicate how much the statement fits them on a 4-point scale. The title on the instrument does not mention suicide. Goldston noted that the cutoff score was not very useful in identifying youth who eventually made suicide attempts. Unlike the SIQ, there is not strong empirical evidence of its usefulness.

A newer set of assessments that I have found very helpful is the Beck Youth Inventories of Emotional and Social Impairment (Beck, Beck, & Jolly, 2005). The set includes five inventories that can be used separately or together with children from 7 to 14 years of age: (1) Beck Depression Inventory for Youth, (2) Beck Anxiety Inventory for Youth, (3) Beck Anger Inventory for Youth, (4) Beck Disruptive Behavior Inventory for Youth, and (5) Beck Self-Concept Inventory for Youth. Each inventory contains 20 items written at second-grade level; the profile is very useful in looking for risk factors. The revised Beck Depression Inventory can be used with students age 13 and older, but the Beck Hopelessness Scale is normed on those age 17 and older. All of these assessments are easy to score and interpret, and have excellent psychometric properties.

Intervention

Crisis response. During a crisis, suicide or other, school counselors must deal with increased demands in a context of heightened tension and anxiety. Nevertheless, the counselor needs to remain calm and supportive. If the student senses panic on the part of the counselor, she or he is unlikely to self-disclose and may even feel guilty for creating distress on the part of the counselor. It is crucial that the counselor not minimize the concerns that have brought the student to this juncture but demonstrate sincere concern and empathy for the student's pain. Despite any personal beliefs that suicide is wrong, immoral, or stupid, the counselor must be nonjudgmental so that the student is not fearful of censure or scolding as he or she talks about suicidal feelings or behaviors. The counselor must do a thorough assessment—ideally, with the assistance of a colleague. The student can be told honestly that the counselor is very concerned and wants to enlist the additional help of Colleague X, who has been helpful in the past in such situations. Then both counselors can consult as to the best strategy for managing the crisis, including notifying parents, contacting outside agencies, and so forth. In many schools, when there has been a concern about suicide, students are required to have an outside evaluation by a qualified professional before returning to school (Capuzzi, 2002).

Many schools and school districts have created crisis response teams so that there are established policies and procedures in place before the crisis emerges, and one does not have to make decisions without guidelines. Crisis teams have organized plans and procedures and have delegated tasks to individuals with specific responsibilities and training. The school counselor should always implement the established crisis response procedure, and enlist the aid and support of team members.

Kirk (1993, pp. 97–99) outlined the steps for a school counselor to take if a suicide attempt is in progress: (1) Ensure the attempter's survival, using appropriate methods (contacting emergency services, administering first aid, etc.). (2) Assess method, gathering as much specific information as possible (type and quantity of drug ingested, location of wounds, etc). This is useful in communicating with emergency personnel. (3) Notify parents or legal guardians. If they are unwilling to respond, contact the appropriate child protective services agency. (4) Activate the school crisis team. (5) Document and report the crisis. (6) Follow-up with emergency personnel in order to be able to provide accurate information to those involved and, later, to serve as liaison with outside agencies to assist the student in reentry to school.

Kirk (1993) also provided useful guidelines when an attempt has not been made but the school counselor has reason to suspect a student is imminently suicidal: (1) Make and maintain contact with the student, making sure the student knows the counselor is listening and concerned. (2) Assess for the existence of a plan and the lethality of the method. (3) Consult with another professional. If possible, the counselor should enlist the aid of a trained colleague. (A strategy for accomplishing this without leaving the student alone will be discussed below.) (4) Notify parents and assist them in making arrangements for immedi-

ate appointment with a professional. (5) Initiate a suicide watch. It is essential that the student not be alone at all, so it may be necessary to involve others while arrangements are being made for parents to arrive. (6) Document the event. (7) Follow up as above.

When a student is at imminent risk for suicide, it is critical not to leave the student alone. It is also important to begin the process of notifying parents and consulting colleagues. It would seem that those two priorities cannot be accomplished at the same time. The use of an established procedure in such events, however, is efficient and effective. For example, in one setting in which I worked, the plan was as follows. If the counselor had a student in the office in a crisis situation, the counselor would tell the student that the counselor just needed a moment to phone to cancel a doctor's appointment. The counselor would then phone (or contact on the intercom) the secretary, telling her to please cancel my appointment with Dr. Codename. The secretary's job was then to alert others to the situation, and send someone to the counselor's office immediately. A similar code can be created to alert teachers of a high risk situation in the school, initiating a prescribed procedure to assure everyone's safety. Depending on the situation, the secretary would alert all members of the building's crisis response team to the situation, so that they are on hand to do whatever tasks are necessary. All procedures need to be clear, in writing, and reviewed on a regular basis; crisis teams should receive ongoing training and support.

No suicide contracts. This is another issue on which there are differing opinions and little empirical data to support either position. There is consensus, however, that a "no suicide" contract should never be the only intervention strategy; rather it should be one of the tools used. Weiss (2001) expressed the preference for less legalistic terminology, such as "no suicide" *pact, agreement*, or *understanding*. Poland (1989) favored the use of "no suicide" contract and recommended a written document on official school stationary. Both counselor and student sign the contract, and both receive copies. The content should include the name of the student and words to clearly state an agreement that if the student is having suicidal thoughts, he or she will contact the counselor (contact info provided), a 24-hour crisis line (number provided), or the nearest adult for help. Range et al. (2002) recommended a specific period (until the next appointment, over the weekend, etc.) because time-limited agreements are easier to keep. These experts also suggest including as one of the options going to the hospital emergency room. They also begin each contract with a statement such as "I want to live long and be happy" (p. 72). This article is an excellent source of sample contracts for children and adolescents.

Additional components of a contract might include agreements to self-care, such as getting adequate sleep and food, how unscheduled time will be structured (e.g., weekends, after school), and most important, an agreement to remove any potentially lethal means from the home, such as guns, other weapons, and medication (Capuzzi & Gross, 2004). Motto (1999) made the point that a "no suicide" contract is only appropriate in the context of a mutually trusting relationship. For the school counselor, this means that a contract is appropriate in the case of a student with whom the counselor has established a solid relationship and who has been open with the counselor about the suicide issue. A student who is referred by someone else and denies any suicidal thoughts is not one for whom such a strategy is appropriate. The student may well sign the contract in order to end the discussion, but is unlikely to have much commitment to upholding the agreement. Miller (1999) referred to a strategy of not asking the client to agree not to commit suicide, but to focus on not taking any action until the client has taken all the steps in the contract (contacting the counselor, going to the emergency room, etc.). The point of this approach is to emphasize to the client that suicide is a permanent solution, and so the counselor wants the client to try everything else before taking such a terminal step. This strategy might have some use in acknowledging the client's pain, but school counselors should be very cautious that this not be interpreted as an endorsement of suicide.

Brent and Kolko (1990) have recommended that the family also sign the contract, which is consistent with the schools' obligation to notify parents when suicide is an issue. They stress that a contract should be considered only when certain elevated risk conditions are not present: current substance abuse, psychosis, or bipolar disorder. The school counselor should follow-up the contract with questions such as, "What would you do if [the precipitant of the episode] happened again?" If the student does not refer to the agreement, there would be a concern about the value of the contract. With children, it is advisable to test their understanding of the contract by having the child repeat or explain the agreement. Kirk (1993) has also supported the use of "no suicide" contracts, which he has stated are useful because they provide structure and time while other interventions are explored and arranged (professional counseling, hospitalization). He added that proposing the contract is a useful way to assess the effectiveness of intervention so far. If the student refuses to make an agreement, that is a signal of the need for a more restrictive intervention (e.g., hospitalization) . On the other hand, Weiss (2001) pointed out that a refusal to sign a contract may also signal that the relationship between the counselor and the client is fragile. Both Poland (1989) and Kirk (1993) also provided examples of written "no suicide" contracts.

Advantages of "no suicide" contracts are that they clearly specify contingency behaviors the student can use other than suicide. Students may perceive the request for the contract as evidence of the counselor's concern, which would strengthen the relationship. These contracts can reduce both the student and the counselor's anxiety in outlining such a specific protocol. In addition, the request for a contract can be used as an adjunct to more formal evaluation of risk by noting the degree of the student's willingness to agree to the contract. The contract also provides partial documentation of the counselor's effort to prevent the suicide (Range et al., 2002).

The disadvantages of the contract include the possibility that older students may see it as an attempt by the counselor to protect against lawsuits, rather than as a measure of concern for the student. It also may be perceived as coercive. There is the danger that the counselor will overly rely on such contracts, which is ill-advised, as the contract should be a component, not the sole measure, of intervention with a suicidal student (Kelly & Knudson, 2000). The counselor may also mistakenly believe that he or she is immune from liability when a contract has been signed, which is not the case (Range et al., 2002). The counselor must also remember that the contract does not eliminate the suicide risk.

What are some best practices to follow if and when a contract will be used? One is not to use a preprinted form, but to design the specifics of the individual contract collaboratively with the student. Students may provide the names and phone numbers of people to contact, and some specific strategies to manage unstructured times; this process gives them more ownership of the agreement. Also helpful is the use of positive wording wherever possible, (e.g., "I agree to keep myself safe"). Best practice includes outlining a specific time period, providing copies to appropriate persons (including parents), and employing a follow-up mechanism (Range et al., 2002).

Postvention

Following the suicide of a student (or staff member), a plan for postvention should be implemented. Ideally, members of the building crisis response team, the school district crisis response team, and community resources will work together to plan the response. Tasks that must be accomplished are (1) providing accurate information to all constituents, including students; (2) assessing survivors who might be at risk for suicide themselves; (3) providing support to grieving students and staff; and (4) dealing with media.

Postvention efforts should begin as soon as possible after the suicide (Leenaars & Wenckstern, 1991). In many cases, if the event becomes known or occurs after school hours, a phone tree can be activated to notify staff and plan a meeting before students come to school. The exact wording on any announcement to students should be agreed upon (and checked by police or other sources for accuracy). It is strongly recommended that such announcements be delivered in classroom groups by regular teachers whenever possible, and at an agreed upon time, so that all students get the same information at the same time.

When students learn of the suicide, there are a variety of possible responses. Many students who knew or were close to the deceased will be visibly upset, and they should be allowed to leave the classroom setting to see the counselor. Group support sessions can be conducted with the assistance of district and community team members. Other students who did not know the student involved may also exhibit grief responses related to other losses they have experienced. If any students had argued with the deceased student, or is being blamed by others for the death, they need to be quickly identified and provided with considerable support. In one case I recall, a popular and talented student committed suicide after being told by his girlfriend that she thought they were getting too serious and that she wanted to spend less time together. Out of their own anger at the loss, many students blamed the girl, saying if she had not broken his heart, he would be alive. The rejection she experienced and the guilt she felt became so intense that she had to change schools in addition to receiving outside counseling.

Parents of students who knew the deceased should be contacted, provided with the same information the students received, and urged to be alert to signs of complicated grief. Any student who might have had negative feelings or interactions toward the student who died may feel increased anger and/or guilt, and should be reassured that it is not one event that causes suicide. The school counselor is often the person who will contact the family of the student who died and offer condolences, especially if there was a prior relationship with the family. The counselor must also be alert to teachers who are particularly impacted by the death and encourage them to gain support.

Dealing with the larger system should be left to other members of the crisis team. The district office must be notified, and team members of that level will deal with media and will also notify crisis teams of other schools who should be notified immediately (e.g., feeder schools, schools attended by siblings of the deceased student). School counselors will undoubtedly be involved in discussions of funeral attendance (will students be excused if the funeral occurs during the school day, will staff be free to go, should there be any memorial at school, etc.) and should be best informed about recommended practices. Memorials are widely discouraged, but each individual case should be considered carefully.

In addition to the immediate tasks of postvention, follow-up will also be in the school counselor's arena. If at-risk students are referred for outside counseling, the school counselor should follow up and ensure that the counseling is occurring. At-risk and grieving students should be monitored so that signs of lingering problems can be observed and appropriate action taken.

Elementary Versus Secondary Counselors

While the roles in prevention, intervention, and postvention are similar at elementary and secondary levels, there are some important differences. Curriculum approaches to suicide awareness are not recommended for elementary students, but classroom guidance lessons that address many of the risk factors for suicide are typically conducted by the counselor. At these times, the counselor needs to be alert to students whose reactions suggest that they need further assessment. Although rare, suicides do occur in elementary students, and any mention of suicidal thoughts or behaviors should be taken seriously, regardless of the age of the child. Elementary counselors usually provide group counseling and guidance to students, and grief groups are not uncommon. Parental contact tends to be more frequent at the elementary level, so counselors may have more information about family climate and changes in the family than do secondary counselors. Secondary school counselors with large caseloads may not have the opportunity to get to know each student well and, thus, may not have had the opportunity to build a trusting relationship with the student who is referred for suicidal concerns. Despite these differences, the roles of school counselors at all levels are much more similar than different.

Ethical Issues

There are a number of ethical standards that apply to the school counselor dealing with suicidal students. The first relates to a student who is a danger to her or himself. The American School Counselor Association's (ASCA) Ethical Standards includes this principle:

> A.7. Danger to Self or Others
>
> The professional school counselor:
>
> a. Informs parents/guardians or appropriate authorities when the student's condition indicates a clear and imminent danger to the student or others. This is to be done after careful deliberation and, where possible, after consultation with other counseling professionals.
> b. Will attempt to minimize threat to a student and may choose to 1) inform the student of actions to be taken, 2) involve the student in a three-way communication with parents/guardians when breaching confidentiality or 3) allow the student to have input as to how and to whom the breach will be made. (ASCA, 2004, p. 2)

This ethical principle makes it quite clear that the counselor is obligated to break confidentiality when the student is a "clear and imminent" danger. Unfortunately, those terms are not defined, and the school counselor is left to consider whether lesser degrees of suicidal behavior (e.g., ideation, vague comments) qualify. It is best to err on the side of caution given the cost of an error in the wrong direction and the inability of professionals to accurately predict suicide.

The other area of ethics that is involved in working with suicide in the schools is professional competence. From the standards:

> E.1. Professional Competence
>
> The professional school counselor:
>
> a. Functions within the boundaries of individual professional competence and accepts responsibility for the consequences of his/her actions.
> b. Monitors personal well-being and effectiveness and does not participate in any activity that may lead to inadequate professional services or harm to a student.
> c. Strives through personal initiative to maintain professional competence including technological literacy and to keep abreast of professional information. Professional and personal growth are ongoing. (ASCA, 2004, p. 4)

Given that school counselors are unlikely to have had sufficient training in their graduate programs, it behooves them to seek opportunities to develop competence in working with all areas of suicide. Professional development opportunities such as in-service trainings and crisis response team trainings can be helpful. Professional conferences and workshops on the topic are another avenue to increasing knowledge and skills. Reading professional literature and staying current are additional measures to ensure that all school counselors are competent to assume their responsibilities on the "front line" of suicide prevention, intervention, and postvention.

Issues of Diversity

Although the majority of completed suicides in adolescents are in Caucasian youth, rates of other groups have been increasing dramatically. Rutter (2004) is concerned that because racial and ethnic minority students may express suicide risk differently, they can be overlooked, and assessments may be inaccurate. With the increasingly diverse population in America's schools, it is essential the school counselors be aware of racial/ethnic differences that might affect how students respond to suicide prevention, intervention, or postvention efforts. Although minority youth are vulnerable to the same risk factors as other youth, they may also be subject to unique risk factors based on their status that elevate risk for suicide. As a result, efforts to reduce suicidality in these youth must acknowledge and respond to these risk factors.

In their study of ethnic differences in patterns of suicide over the lifespan, Garlow, Purselle, and Heninger (2005) examined records of suicides in Fulton County, Georgia, from 1994 through 2002, and found that rates and patterns mirrored those reported in national samples. As in other studies, African Americans commit suicide at lower rates than Whites, and females had the lowest rates of all groups. Among victims younger than age 20, significantly fewer Black youths tested positive for substances at time of death than did Whites in the same age group. In attempting to account for their findings, these researchers noted that although the rates of psychiatric disorders (including depression) have been found to be similar in both groups, the availability of mental health treatment for African Americans is limited and is of lesser quality. Perhaps as a consequence, young African Americans may be reluctant to seek treatment. On the other hand, African American culture may mitigate against suicide. The protective factors of family support and religiosity are suggested to explain the overall low rates of suicide in this group, and the widely held attitude among African Americans that suicide is not acceptable also may serve as a protection. School counselors need to access the community support, and in an intervention it would be advisable to consider including extended family members as well as clergy. Based on this study, the best prevention strategies would be those that serve to strengthen the protective factors (e.g., educating parents and involving them in school programs) and those that include screening for depression.

Although Latino youth in the United States commit suicide at lower rates than other ethnic groups do, they are much more likely (particularly females) to make suicide attempts (Canino & Roberts, 2001). The Latino or Hispanic group is not homogeneous, and although the following discussion will generalize some concepts, there are intragroup differences depending on country of origin. Suicide ideation and attempts of Latino-American youth (Mexican American, Cuban American, and Dominican American) are higher than rates among comparable youth in their country of origin. This fact may indicate that acculturative stress is responsible for the increased ideation and attempts. A detailed discussion of that concept is beyond the scope of this chapter, but acculturative stress refers to a group of stressors such as conflicts in values between cultures, perceived discrimination, language difficulties, and perceived poor opportunities. Family support and positive expectations about the future appeared to protect against acculturative stress and, thus, protect against suicidal behaviors. Canino and Roberts also cautioned that as most studies of rates of suicide among adolescents are conducted in school settings, the many Latino youth who drop out of school (approximately 30%) and are probably at higher risk for suicide are often excluded from the data, presenting a false picture of the resilience of this group. No suggestions are offered for school counselors, but it would be wise to consider acculturative factors in planning suicidal prevention, intervention, and postvention. The protective factor of family support is important, but many school counselors face a language barrier when communicating with Spanish-dominant or monolingual Spanish-speaking parents about their students. Parent training and education programs are usually presented in English, excluding those parents who are not fluent in the language. In addition to recruiting more bilingual counselors, current school counselors need to make special efforts to collaborate with parents of those students so that the school and home can work together to prevent suicide.

American Indian youth have the highest rate of suicide among all groups. These youth experience many of the risk factors of other groups, but also have added risk factors unique to this group: social disintegration and cultural conflict (Metha & Webb, 1996). While some tribes have maintained their separate cultural identities, others have integrated with the majority culture. For many American Indian youth, adopting the majority cultural values means a loss of pride in their culture and decreased self-esteem. High rates of alcoholism and suicide may be the effect of "social alienation, social confusion, and self-hate" (p. 25).

Gary, Baker, and Grandbois (2005) have stated that suicide among American Indian youth is a fatalistic suicide, a reaction to the historical regulation by the dominant culture, including loss of their land, exploitation of natural resources, forced relocation, and forced assimilation. These experiences have led to pessimism about the future, and suicide may be the result. Living conditions on many reservations are substandard, with high unemployment and inadequate health and education facilities and services. In addition to the high rates of suicide, these authors point out that American Indian youth die at high rates from pre-

ventable injuries, some of which may actually be suicides. Previous research found that for a large sample of Navajo adolescents in grades 6 through 12, risk factors for suicidal behavior included feelings of alienation from family and community, having a friend who made a suicide attempt, and use of alcohol on a regular basis. Family history of suicide, a history of physical abuse and violence in the family, and sexual abuse were additional risk factors. Protective factors were also detected. Girls were protected by attention in the family, positive feelings about school, and caring by family and other adults. For boys, positive experiences at school, participating in traditional activities, good academic performance, and caring by family and other adults were the most prominent protective factors. For both boys and girls, support and caring by tribal leaders was a protective factor. Another previous study on Northern Plains reservations found that commitment to cultural spirituality was associated with reduced suicidal behaviors. In addition to common risk factors, an additional risk is the presence of guns in the homes. As many American Indians hunt for food, guns are among the basic tools found in the homes of many families.

Metha and Webb (1996) cited LaFramboise and Bigfoot (1998), who observed that the governmental pressures to assimilate (via boarding schools and prohibition of native language use in government schools for many years) may have created only one road to freedom: suicide. Further, some cultural attitudes may make suicide a more viable option to at-risk youth. The self-control that is admired in the culture may cause some youth who are experiencing psychological problems to internalize those problem. In some tribes, death is not as feared as it might be in other cultures, and the belief in ongoing contact between the human and spirit world may diminish the fear as well. In some tribes, large ceremonies (sometimes involving giveaways) that occur after a death, including a suicide, may be attractive to vulnerable youth.

Implications for schools counselors include the high need for suicide awareness programs for American Indian youth (Metha & Webb, 1996). Parent education is also crucial and often difficult to implement. Outreach to parents should be ongoing and should use personal visits and tribal liaison personnel to encourage involvement in school programs and activities. To increase attendance at programs for suicide awareness, school counselors can encourage the use of raffles and food as an incentive for attendance and can also support the use of tribal members as speakers. Finally, staff training in suicide awareness for professionals working with American Indian youth should be mandatory and should include follow-up sessions on a regular basis, to increase vigilance about adults who have many opportunities to observe and interact with the youth.

In addition, intervention strategies should employ traditional native practices (such as the healing circle and the medicine wheel), and the role of the school counselor might be to refer to tribal sources for these practices. When the only mental health providers are non-Indians, the use of traditional healers is especially important to avoid conflicts with cultural beliefs. In addition to involving parents when a student is at imminent risk, bringing members of the extended family into the consultation may increase the effectiveness of the intervention. As involvement in traditional cultural practices is a protective factor, encouraging and supporting that involvement is a useful preventive effort (Gary et al., 2005).

Although no literature on suicide in Asian American/Pacific Islander children and adolescents was located, suicide is the third leading cause of death in youth from 10 to 24; this group should not be ignored in efforts to reduce suicide among students. Chung (2002) noted that Asian American youth are considered to be prone to depression. She cited racism, the absence of Asian teachers and professionals in the school system, conflict with parents (students are likely to be more acculturated than parents are), and parental emotional unavailability as unique risk factors for this group.

Non-heterosexual youth are also at higher risk for suicide than their heterosexual peers (Russell, 2003). For this group, an additional risk factor is the possibility of abuse from relatives and family members who reject the child's sexual orientation. These students are often victims of violence and bullying at school as well. The adolescent task of identity formation may be difficult for sexual minority youth because of societal attitudes (Kirk, 1993). Social support from other LGB peers, family support, and self-acceptance of the sexual minority identity are protective factors. School counselors must be available to these students and must advocate for measures to protect them in the school environment. Further, with student consent, school counselors can provide parents with information about community resources that might be helpful as they adjust to their child's sexual orientation.

Overall, members of these diverse groups experience additional risk factors not present in Caucasian students. School counselors must be sensitive to these differences and must work to provide programming that is responsive to the needs of all students. Ideally, we would have a more diverse population of school counselors; presently, school counselors would do well to create collaborative relationships with diverse professionals who work in other settings whom they can call upon when needed.

Future Directions

There appear to be two needs in which future work in this area should focus: (1) research and (2) training. For school counselors, accountability has become a watchword, and in an area as important as suicide, they should be able to examine the evaluation of prevention programs to make evidence-based decisions for their schools. To date, such research has not provided the counselor with solid evidence of the effectiveness of any program, although some are better evaluated than others and seem promising. The availability of federal dollars to assist in establishing programs is good news, but unless schools incorporate stringent evaluation designs, those dollars may not be well spent.

School counselors are the logical choice of professionals to take leadership in suicide prevention/intervention/postvention efforts in their schools. To do so requires that they receive the best current information and training available. When this training is not provided in schools, counselors should be strong advocates for change. Further, school counselors must keep informed of opportunities for training outside of their local school or district and seek support for attendance at such conferences. Belonging to professional organizations is one way to keep up to date with new research and practices. The task of dealing with suicide is a daunting one, and school counselors need to be armed with the best information and training possible.

Shneidman (1987) said that "the most dramatic and tragic of all suicides (as a group) . . . is suicide among the young" (p. 178). School counselors have a unique role in schools, and they have the opportunity and the duty to reduce these tragic deaths. In this difficult work, it is easy to focus on the few tragic losses. Counselors must also focus on the many students whose path toward suicide was diverted by a competent and compassionate school counselor.

XXXVIII
WORKING WITH SCHOOL FAILURE

KAREN A. CORT
Teachers College, Columbia University

Introduction

In the United States, the educational system has become a significant medium for the preparation of children's transition into adulthood. Contemporary school systems are responsible for imparting basic academic knowledge and skills and didactic job-skills training, as well as assuming many of the socialization functions that earlier had been the sole responsibility of the family (J. J. McWhirter, 1998). Also consider that the school is the location in which children spend 30% to 40% of their waking hours, has mandatory attendance from about age 5 to at least 16 years, and is a primary source of constant evaluation of their performance (which oftentimes determines the child's level of aptitude for his or her lifetime; Harvey, 1984). As such, the effect of the schooling process probably has a more meaningful impact on the development of the individual than any other social institution. Therefore, outcomes of school must play an important role in the outlook and future livelihood of students. Unfortunately, though, the outcome for too many students in school is that they have not been able to satisfactorily fulfill the expectations placed upon them, and thousands of students "fail" the school system.

When students fail to achieve, there are numerous implications and consequences that may occur above and beyond their overall individual achievement level. Students with failing grades are at risk to fall down a spiral that can derail their educational and occupational trajectories well into adulthood (Needham, Crosnoe, & Muller, 2004). Academic struggles predict short-term problem behaviors and may eventually lead to dropout, creating disorder and undermining the general mission of schools. Moreover, as the United States faces global economic competition, children at risk for school failure represent a subgroup of the population whose fate will help shape the future of this country. High levels of school dropouts will cause the country to squander money, as society pays six times more to maintain an uneducated adult than it pays to keep a student in school through graduation. These trends will lead to billions of dollars in lost earnings, further expansion of welfare, and criminal justice expenses for this country, and will ultimately make the United States less economically competitive in the world (Becker & Luthar, 2002). Thus, what appears to be merely an aspect of the adolescent experience actually has far-reaching consequences across a variety of social phenomena. Children and adolescents who fail become "a problem" not only to the school system that was created to serve them, but also to society in general.

School failure is often viewed as a negative consequence to an individual student's actions and/or behavior. The burden of school failure is often placed upon the individual student particularly because in the U.S. educational system, student advancement is predicated on individual effort and graded performance in a series of classes. When students don't pass, it becomes their fault—often because they are "lazy" or "not trying hard enough." While some students do not live up to their potential, lack of effort alone cannot explain school failure, especially when one examines the discouraging statistics demonstrated in the disproportionate numbers of adolescents of color who "fail" and completely drop out of the educational system (approximately 50% of Black and Latino students combined in the year 2001; U.S. Department of Education [USDE], National Center for Educational Statistics [NCES], 2005; also see Coleman, Chapter X, this volume).

Placing the sole responsibility for the problem of school failure upon the student is narrow and skewed. This individualistic perspective does not acknowledge the fact that people's functioning is dependent upon their unique

strengths and deficits, who or what they interact with on a daily basis, as well as those systems that structure the individuals' day-to-day realities. Ecological systems theory provides a conceptual foundation for emphasizing individual development within the immediate social environment and the impact of the larger social context on this environment (Neville & Mobley, 2001). Utilizing an ecological model provides a systematic and comprehensive approach to understanding the "bigger picture," identifying those personal, as well as environmental, factors contributing to a student's performance. Examining school failure from a broader ecological perspective places one in a stronger position to both better understand the source or sources of the student's difficulties and identify a range of possible responses and interventions (Abrams, Theberge, & Karan, 2005). Instead of focusing primarily on the student, an ecological approach would simultaneously recognize and, at times, carefully modify the balance between the person and the systems that interact both directly and indirectly with that person to organize his or her behavior. Working from an individualistic perspective—focusing on only the person or the system by itself—will not likely demonstrate sustained improvement and may simply contribute to the dilemma of "failing students." This may explain why our nation is becoming less competitive with other countries, as well as our consistent 11% dropout rate (for the past 15 years) and increasing numbers of students of color dropping out of the system, despite all of the research efforts to date, high-stakes testing, and dollars spent in educational reform. Think about it: How effective can individual change be if the individual has to return to a "sick" system?

In this chapter, school failure is examined from an ecological perspective, not as a discrete, unitary diagnostic category of an individual. More specifically, *school failure* is defined as a set of presumed cause-and-effect relationships among individual and environmental dynamics that place a child or adolescent in danger of negative future events in school (J. J. McWhirter, 1998). The purpose of this chapter is to explore school failure along a continuum, examining four different degrees of "failure"—academic failure, truancy, grade retention, and dropout. Each degree of school failure will be examined in terms of the varying ecological trends and contributing factors that define the problem. The chapter will conclude with practical strategies and suggestions, from an ecological perspective, that school counselors can utilize to address the needs of students who "fail."

Academic Failure

Academic achievement is generally known as student performance in school as measured by grades. Academic failure is, therefore, defined as the failing performance of a student because he or she receives extremely low grades (e.g., "F") in a class(es) (Dimmitt, 2003). Academic failure generally is thought of as the first step in the continuum of school failure (Kaplan, Peck, & Kaplan, 1997). The variable most directly related to academic failure is poor academic performance in the classroom. However, a student's academic performance can vary considerably between content areas (e.g., science, mathematics) and over time. Poor performance in one content area does not necessarily generalize to other areas. For example, according to the National Assessment of Education Progress (NAEP), fourth graders' average reading scale score has not been significantly different in the past 10 years (approximately 40% of students consistently perform below the basic level nationwide), while fourth graders' average mathematics scale scores have changed significantly in the same time period, with student performance steadily improving (50% of students below basic level in 1992 decreased to 35% in 2003; USDE, NCES, 2005).

Failing to achieve passing grades often disables students in a number of ways. When a student fails, he or she is often restricted from entering more rigorous curricula and may be subjected to repetitious, remedial course work. Moreover, "no pass, no play" policies in many school districts prevent students who have failed courses from participating in extracurricular activities (many of which have positive influences on child and adolescent development; Needham et al., 2004). Low-performing students are less likely to graduate from high school and less likely to go on to college, directly affecting their future adult financial livelihood, as most high school dropouts and people who don't attend college earn substantially lower wages than those who do (Kaplan et al., 1997). This has been found especially among rural youth. Only 54% of rural students apply to college, compared with 62% of their suburban peers (Hines, 2002).

Furthermore, calls for educational accountability over the past 2 decades have resulted in a move toward enhanced graduation requirements and mandated proficiency tests. Implementation of high-stakes testing and school accountability policies has escalated, broadening the consequences of academic failure. Academic achievement and failure has advanced beyond school grades and has become equated with student-outcome scores on standardized tests. Proficiency tests alone are often being used as a blanket measure of school success, making it possible for those outside of the school system to selectively apply test results to bring sanctions against teachers and schools that are floundering (McEvoy & Welker, 2000). This is reflected in the current federal policy incorporated within the No Child Left Behind Act, which identifies schools as needing improvement if their overall performance does not improve from year to year, or if subgroups do not make adequate yearly progress (Christenson & Thurlow, 2004). These new actions on the surface seem to be attempting to address the need for

school reform and appear to be raising the standards of education in the U.S. school system. Unfortunately, however, these same actions are also placing unnecessary pressure on students creating another area in which they can possibly fail, as well as increasing the numbers of students who are becoming academic failures. For example, urban students are less likely to meet the minimum standards on national tests and less likely to complete high school in 4 years (Lee, 2005). Moreover, rural and urban students consistently scored at about the same level in math, reading, and writing, but significantly lower than their suburban cohorts in the same areas (Hines, 2002).

In addition, some teachers' attitudes are changing toward students due to these systemic pressures. Many teachers, in particular in urban areas, whose professional success tends to be measured by the percentages of their students who pass standardized tests, are beginning to adopt a militant "sink or swim" attitude toward students. Some have developed a tendency to pressure students to perform and may also concentrate their efforts only on those students who are perceived as being able to "swim" (McEvoy & Welker, 2000).

Factors Contributing to Academic Failure

Individual Factors

Academic failure has been linked to several factors intrinsic to students. These include cognitive deficits, attention problems, mental health challenges, and behavioral difficulties (McEvoy & Welker, 2000). Moreover, student motivation is another significant factor that may influence academic failure. Often, student's beliefs about and perceptions of the futility of school, as well as the value of specific subjects may often detract from their level of motivation and effort toward their academic progress (Dimmitt, 2003). In addition, students who lack the social skills to develop friendships, as well as those who perceive rejection by students and teachers, are at high risk for academic difficulties (Kaplan et al., 1997). Students who do not have social skills and/or positive relationships at school often lack the daily social support that enhances and contributes to positive academic performance. Lastly, lack of homework completion has also been found to be a significant individual factor contributing to academic failure. Homework is often used as a tool for reinforcement of class work and new material, as well as an opportunity to practice and improve skills. When homework is not completed, a student becomes at risk for academic failure. Material presented in class often builds upon previous material. If the student did not comprehend or become proficient with this material, the student begins to have gaps in his or her learning that often make subsequent learning difficult, and eventually impossible in some cases. This was supported in a study conducted by Dimmit, in which students, parents, and teachers were asked why they thought students were failing specific classes. All three groups identified not doing homework as the most significant factor (70% of teachers, 73% of parents, and 61% students).

Family Factors

Families have a tremendous impact on what happens to students in schools. The most significant family factors that are related to school achievement are the amount of family involvement with the school and family attitudes and beliefs about schooling. Parent–teacher communication and parental expectations of academic success also affect student achievement. When a student and/or the school are aware that family members are monitoring their child's progress, a greater interest arises. These external supports help students feel more motivated and supported for their efforts. Moreover, within the school, the student begins to receive greater attention, as faculty and staff recognize that this child's family supports his or her efforts and are willing collaborators. This makes their job easier and more effective.

There are also family factors that are not directly related to school–family relationships that have an impact on student success. These include family cohesion (e.g., divorce or death of a parent), lack of structure and instability, ineffective and inconsistent discipline practices, lack of parental supervision and monitoring, and little parental education (Dimmitt, 2003). These factors may cause family stress. Often stressors detract from family attention and school involvement, leaving no structure to guide the student and little support for the student to depend on. Another consequence of family instability and stress may oftentimes lead a child to change schools frequently. Changing schools impacts the coherence of students' academic experience and can result in knowledge gaps, lack of school connections, and the absence of appropriate educational service (Dimmitt).

School Factors

In the broadest sense, the general school climate has a tremendous impact on how all the people in the building—students, teachers, and administrators—feel about being in that environment. Students are more likely to do well when there is a school culture that has an academic emphasis, and when there are adequate educational resources to provide support for student learning within the school (Dimmitt, 2003). In addition, school practices, such as ability grouping or tracking, dramatically affect student concep-

tions of ability and sense of futility. For academically failing students, placing them in low-achieving "ability groups" or tracks with low expectations for academic success is especially detrimental to their subsequent school performance and to their nonacademic behavior. Tracking also heightens tensions and promotes segregation between groups ("failures" and "achievers"; McEvoy & Welker, 2000).

Teacher expectations and judgments of student's academic ability are also strong contributors of academic failure. Student perceptions of their academic ability and a sense of academic futility are greatly influenced by their teachers, as they are often the dominant daily reinforcement in a student's world. Students who are involved with teachers who do not hold a widely shared belief that *all* of their students will master grade-level objectives, irrespective of their background and life circumstances, have less support within school and are at greater risk for failure (McEvoy & Welker, 2000).

Community/Societal Factors

The complex interaction of culture and race must be taken into consideration when considering school failure. Many schools in this country continue to have students of color primarily being taught by White teachers. As such, curriculum, materials and/or didactic methodologies often reflect White American middle-class culture and not the range of learning styles and cultural experiences of all students in the classroom. This may result in students of color being at risk in school because their experiences and different learning styles are discounted, misunderstood, and not appreciated but instead viewed as pathological (Dimmitt, 2003).

Academic failure is the first step along the continuum of school failure. Historically, academic failure was measured only in terms of grades and G.P.A. However, in recent years, with the implementation of educational reforms, such as the No Child Left Behind Act, academic failure has included such measures as standardized testing. These efforts not only have caused stress and pressure among students and school faculty, but have also increased the number of academic "failures."

From an ecological perspective, a number of factors have been explored that contribute to academic failure. These include individual factors, such as cognitive deficits, lack of motivation, and lack of homework completion. Several family factors were also discussed, including the amount of family involvement and family attitude toward school, as well as family stress. School culture and teacher expectations have also been found to contribute to academic failure. Lastly, the influence of the broader context of dominant White Eurocentric American culture was examined to demonstrate its possible impact on academic failure.

Although academic failure is detrimental by itself, there are other levels of school failure. Often as a consequence of academic failure, the next more destructive level of school failure—truancy—occurs.

Truancy

Truancy is defined as a student's repeated unlawful and willful absence from school without knowledge and consent from parents (Kearney, 2003). In broad terms, truancy includes several school refusal behaviors, such as repeated tardiness in the morning, repeated absences and/or difficulty remaining in classes for an entire day, complete absenteeism for a certain period of the school year, to the extreme case of complete absenteeism for an extended period of time (Kearney).

Truancy is often used as a coping mechanism due to negative feelings toward school and/or can be utilized by some as attention-seeking behavior. It can begin as a result of academic failure, but may be due to other reasons. Regardless of the initial motivation, truancy can interrupt social development and has been identified as a precursor to undesirable outcomes and negative consequences in childhood, adolescence, and adulthood (McCluskey, Bynum, & Patchin, 2004). Short-term consequences include declining grades, legal difficulties, social alienation, family conflict, and distress (Kearney, 2003). Long-term consequences of truancy include academic failure, juvenile delinquency, school dropout, and occupational and social problems in adulthood (e.g., lower status occupations, less stable career patterns, and higher rates of unemployment; Kearney).

The inclination to miss school increases significantly by grade level. Skipping school accounted for 9% of all days eighth graders missed in 2000, compared with 16% for tenth graders, and 26% for twelfth graders (USDE, NCES, 2005). School systems do recognize the damaging effects of high levels of absenteeism and appoint truancy officers to search for missing students, particularly those in secondary schools (McCluskey et al., 2004). However, the issue of truancy has largely been ignored on the elementary school level.

Factors Contributing to Truancy

Individual Factors

A variety of factors is associated with truancy at the individual level. Poor social and cognitive skills, health problems, learning disabilities, and emotional disorders have all been found to influence the school experience generally and ultimately affect school attendance (McCluskey et al., 2004). Among elementary school students in particular,

cognitive skills can affect coping and self-perception. Often if a student has low comprehension of class material or is not as competitive academically in comparison with his or her peers, he or she experiences negative feelings, such as frustration, anger, and sadness. As a coping mechanism to avoid these feelings and their negative perceptions of themselves, students begin to avoid school attendance. In addition, social skills can influence the ability of children to develop relationships with teachers and other students. Those with awkward or immature social skills may have a more difficult time acclimating to school and making new friends year to year. This may contribute to a consistently unpleasant experience day to day, year to year, increasing the likelihood of absenteeism and potential truancy (Barth, 1994).

Parent and Family Factors

Parent and family factors have been linked with school absenteeism. These include chaotic family structure, alienated families, poor parenting skills, and child abuse/neglect. Children and adolescents who are members of chaotic families often lack structure, support, and resources—all of which are necessary to maintain school progress. It is more difficult to attend to a child or even notice his or her infrequent pattern of attendance when there are too many distractions and other potential stressors (McCluskey et al., 2004).

School Factors

School characteristics that have been linked with school attendance broadly include teachers and the larger school environment. Teachers who are supportive of students and those with high expectations for student achievement are likely to encourage attendance and are also more likely to have higher attendance rates (McCluskey et al., 2004). In addition, schools that have consistent and stricter enforcement of attendance policies are more likely to have fewer problems with truancy (Kearney, 2003). For example, McCluskey and his colleagues conducted a study with chronic absentee elementary school students. A significant increase in attendance was found when the school enforced stricter attendance policies, such as sending a letter home to parents informing them of their child's attendance problem, along with a visit by the school attendance officer.

Student absenteeism also has been significantly associated with school climate. When morale is higher and when students and teachers feel physically and emotionally safe in the building, students are more inclined to attend school. However, in schools characterized by teacher reports regarding students with weapons and increased physical conflicts among students, higher rates of truancy, tardiness, and absenteeism can be found, as students have no desire to attend and be part of such an environment (Lee, 2005).

Community/Societal Factors

Among the larger community characteristics, the presence of delinquent peers and street gangs also contributes to truancy. As children age, the importance of school and community (peers in particular) emerges and negative influences in the surrounding community may serve to detract and coerce students from attending school (Garry, 1996).

Truancy is another level of school failure and is defined as a student's repeated willful absence from school without parental knowledge and consent. The reason for truancy may vary. However, it is often used as coping mechanism to deal with negative experiences in school and can have many short-term and long-term consequences. Among the individual factors that contribute to truancy, poor social and cognitive skills rank highest. Chaotic family structure has also been linked to chronic absenteeism and truancy. Finally, the surrounding communal environment has also been shown to contribute to distracting and coercing children and adolescents away from school, leading eventually to truancy for some.

Truancy is another degree of school failure, but unfortunately there are more severe levels along the negative continuum. Along that continuum, the next level is grade retention.

Grade Retention

Grade retention is the practice of not promoting students to the next grade level (Randolph, Fraser, & Orthner, 2004). The rationale behind this method of intervention is that by repeating the previous year's instruction, children will "catch up" with their new grade cohorts (McCoy & Reynolds, 1999). Back in the 1960s, social promotion (movement from one grade to the next based on age rather than achievement) was employed to reduce the stigma associated with not achieving and progressing academically. However, concern about social promotion grew in response to numerous reports on the deterioration of the American educational system. Some educators fought for the return to academic standards as the basis for promotion. Consequently, many school districts today around the country have established minimum promotion and graduation standards. Grade retention has returned as a popular method of remediating poor academic performance, where an estimated 1 in 5 children has been retained at least one time by the time he or ahe has reach third grade (Alexander, Entwistle, & Dauber, 1994), especially because teachers

and principals are often being held more accountable for student performance.

Although grade retention is used as a strategy to strengthen academic performance, research has consistently demonstrated that the benefits don't outweigh the costs. Results of longitudinal retention research consistently demonstrates that grade retention fails to provide greater benefits to students with academic or adjustment difficulties than does promotion to the next grade (Jimerson, Anderson, & Whipple, 2002). By sixth grade, the emotional well-being of retained students was significantly lower than that of their same age, nonretained peers. Also, by the time they reached high school, the academic adjustment of retained students was significantly lower than that of their never retained peers (McCoy & Reynolds, 1999). Moreover, when students were compared with their "low-achieving but promoted" peers in high school, retained students were more likely either to have enrolled in alternative educational programs or to have dropped out of school (Jimerson & Schuder, 1996). In general, grade retention increased the risk of school dropout from 30% to 50%, regardless of socioeconomic level (Jimerson, 1999; Grissom & Shepard, 1989). The major indication is that grade retention does not appear to benefit many of the children it is designed to help. For all achievement comparisons, the research has shown that retained children consistently and usually significantly underperformed compared with their promoted peers (Randolph et al., 2004; Rumberger, 1995).

Factors Contributing to Grade Retention

Individual Factors

Several factors have been found to contribute to grade retention. Children who are retained tend to have lower cognitive skills and abilities, especially in reading and mathematics test scores and standardized achievement tests (prior to retention). In addition, retained students often demonstrate poor classroom conduct, poor social skills and peer relationships, and low self-esteem (Blair, 2001; McCoy & Reynolds, 1999).

Parent and Family Factors

A number of significant family factors contribute to retention. These include low parent educational attainment (e.g., high school dropout), socioeconomic disadvantage, frequent school changes or residential instability, and lack of parental involvement (Blair, 2001; McCoy & Reynolds, 1999). Children are also more likely to be retained when their parents view them as being less capable. When children are viewed as less capable by their parents, there are fewer expectations of their success. Consequently, teachers' recommendations for retention often go unchallenged by these parents and alternatives to retention are not pursued (McCoy & Reynolds).

School Factors

Teacher expectations are an important factor contributing to grade retention in particular because they are a source of daily reinforcement. When teachers have low expectations and perceptions of a student's academic competence, at times a self-fulfilling prophecy ensues (Blair, 2001). There are fewer expectations for success placed upon the student, and instead the child is viewed negatively. Since no one expects the child to do well, he or she lives up to these limited expectations. Self-fulfilling prophecies do occur, in particular with students from marginalized groups (Jussim & Harber, 2005).

Community and Societal Factors

Unfortunately retained children are more likely to be from racial/ethnic minority groups (Meisels & Liaw, 1993). This in part may be due to racism, which is an entrenched part of the normative American culture and, as a consequence, is transmitted and perpetuated through the various social institutions, including schools (Harvey, 1984). At times, racial/ethnic minorities face a cultural discontinuity between the day-to-day experiences that they encounter in their homes and neighborhoods and the philosophical ideals presented as fact in their school curriculum (Allen & Boykin, 1992). These stark differences at times cause confusion for children of color, who are ultimately forced to either conform to ideals they may not understand nor believe in or else be retained in the system until they learn and espouse values and ideals that ultimately may not benefit their well-being.

Grade retention occurs when a student is not promoted to the next level. In the past, social promotion (movement from one grade to the next based on age rather than achievement) was frequently practiced, and often students were not retained. However, social promotion was abandoned by most school districts due to the belief that this practice weakened the American educational system. Although grade retention is a common practice in contemporary society, research continually demonstrates the harmful effects of this practice on overall student performance and progress.

As with other levels of school failure, individual, family, and societal factors were examined. Individual factors contributing to grade retention were similar to other levels of school failure and included poor cognitive and social skills and abilities. Parental and teacher expectations and

perceptions were found to greatly contribute to those students who were retained. On a broader, societal level, the impact of racism and cultural discontinuity among children of color was discussed as a major influence among those students who are retained.

Thus far, three destructive levels of school failure have been examined: academic failure, truancy, and grade retention. The final and most detrimental level that defines the continuum of school failure is often a result, consequence, or culmination of the other three levels. This level is known as dropout.

Dropout

A *dropout* is defined as a pupil who leaves school before his or her program of study is completed, before graduation without transferring to another school (M. J. McWhirter, 1998). Thousands of American youth are school dropouts, with an estimated 1 in 8 children never graduating from high school (Christenson & Thurlow, 2004). In fact, approximately 11% of the 35.2 million 16- to 24-year-olds in the United States in 2001 were not enrolled in a high school program and had not completed high school, and this estimate has not changed significantly since 1990 (USDE, NCES, 2005). Dropout rates are highest among the most vulnerable student populations including students with emotional and behavioral disabilities (half of whom dropped out of school in 1998–1999), students who are from low-income backgrounds, and those who attend rural and urban schools (approximately 12% dropout rate in these settings; Christenson & Thurlow, 2004; Hines, 2002). Moreover, dropout rates are disproportionately high for Black (11%) and Latino (27%) students, and this statistic has also remained fairly constant since 1990 (USDE, NCES, 2005).

These dropout statistics are particularly alarming because jobs that pay decent wages and benefits have virtually disappeared for youth without high school diplomas. High school dropouts may find themselves without the skills or qualifications to acquire secure, well-paying jobs with potential for advancement (McCluskey et al., 2004). The economic impact of school dropout is reflected in both short- and long-term loss of career options and earning potential. On the average, high school graduates earn $6,415 more per year than high school dropouts. Over their lifetime, high school dropouts can expect to earn $200,000 less than the students who graduated from high school. Not only are dropouts being paid less, they also are at increased risk for unemployment. The unemployment rate is approximately 4 times greater for high school dropouts than for graduates (Lever et al., 2004). As a result, high school dropouts have higher rates of unemployment, are more likely to receive public assistance, and earn less money when employed than do high school graduates (M. J. McWhirter, 1998). Moreover for society, the costs of dropping out are staggering, estimated in billions of dollars in lost revenues, welfare programs, unemployment programs, underemployment, and crime prevention and prosecution (Becker & Luthar, 2002).

Factors Contributing to Dropout

Individual Factors

The decision to leave school without graduating is not an instantaneous one, but rather a process that occurs over many years. Research shows that leaving school early is the outcome of a long process of disengagement from school (M. J. McWhirter, 1998). Dropout is preceded by indicators of withdrawal (e.g., poor attendance and/or truancy) or unsuccessful school experiences (e.g., academic failure and grade retention) that often begin in elementary school (Christenson & Thurlow, 2004). Other factors shown to be associated with dropout include low self-esteem, frequent confrontation and lack of acceptance by teachers and peers, low involvement in extracurricular activities, and a general dislike for school (Lever et al., 2004).

Parent and Family Factors

The major family factor associated with dropout is lack of parental support and supervision. In a study conducted by Rumberger (1995), students who reported less parental supervision had 34% higher odds of dropping out than other students did. Moreover, students from homes with parents who have lower expectations regarding school performance, as well as a low regard and attitude toward education in general tended to leave school before graduating (M. J. McWhirter, 1998). In addition, lack of educational resources and support in the home (e.g., study aids, books, computers) contributed significantly as a factor to increase dropout (M. J. McWhirter, 1998).

School/Community/Societal Factors

Dropouts rarely mention a lack of desire to learn as a reason for their decision to leave school. A lack of relevance between the school's curriculum and the circumstances of student's lives as well as a lack of belongingness are often major reasons. This is especially significant for racial/ethnic minorities in the U.S. educational system. Many of the students who do not graduate are the victims (at least partially) of school systems that failed to understand and respond to their legitimate educational and cultural differences and needs. Schools cannot effectively educate children without

giving consideration to the economic, cultural, and familial contexts from which they come (M. J. McWhirter, 1998). We all don't come from White middle-class families with two heterosexual parents and lots of resources and support.

Dropout is considered when a student "officially" or "unofficially" leaves school before his or her program of study is complete, without transfer. This is the most extreme and detrimental level of school failure. Dropout rates have been found to be steady and are consistently found among the most vulnerable student populations. Dropping out of school has been found to have lifelong economic and financial negative consequences, not only for the individual but also for society in general.

It is important to recognize that dropout is rarely a quick decision and is often a long process of slow disengagement from school. The typical dropout has already experienced many of the other levels of school failure, including academic failure, truancy, and grade retention. Dropouts also don't receive much social support from their families, school environments, and society in general.

Summary

Four levels of school failure have been discussed: academic failure, truancy, grade retention, and dropout. Each level has unique defining characteristics, but unsurprisingly all of the levels have similarities. Each level involves students who are struggling with their social and cognitive development, have limited or no social support from family and the school environment, and often find themselves culturally disconnected from values and ideals of the system that they are mandated to attend. Consequently, these students fail the school system, impacting their personal and professional livelihood forever.

Identifying the "problem" is not enough. It is important to make efforts toward change and decrease all levels of school failure. School counselors need to be involved in these intervention and/or prevention programs and efforts throughout school systems nationwide because they occupy a key position within the school environment. The next section will discuss the role of school counselors in working with school failure, discussing various interventions and/or preventive efforts they can employ in an effort to abolish school failure.

Practice—The Role of the School Counselor

School counselors are an essential factor in working with students who fail in school. It is their goal, according to the national standards for school counseling, as school counselors to facilitate, promote, and enhance academic, career, and personal/social development for the total student population in school (Baker, 2000). However, the wide-ranging demands of helping to improve the academic achievement of students who have not previously received full benefits from the educational system (and have consequently "failed") are challenging, especially as counselors continue to have large student-to-counselor ratios and deal with increasingly difficult, diverse student problems and parental issues. In addition, school counselors often are also required to spend a great deal of time on administrative tasks and other duties unrelated to their position and/or training, sometimes reaching up to 40% of their time (Gysbers, 2004). Moreover, as a result of federal interventions as No Child Left Behind Act, school counselors are facing increasing pressure to demonstrate how the work they do with students contributes to avoiding school failure and increasing student academic achievement (Baker).

School counselors can become more effective in their roles if they become more flexible, adopting an ecological approach to their work. From an ecological perspective, counselors should consider and incorporate factors inherent within the student, as well as factors within the student's environment (i.e., school, family, and community; Abrams et al., 2005) An ecological framework recognizes that each individual's life is affected by the attitudes and ideologies of his or her environments and considers interventions that address some of the pressures and stressors on students' lives stemming from these influences. Interventions may focus not only on addressing the individual student (e.g., direct individual counseling services), but also on more broad systemic levels of intervention, such as the student's family, school, community, and/or others having either direct or indirect influence on that student. The following are recommendations for school counselors from an ecological framework, to effectively work with students who are failing within the school system.

Individual Level

The Counselor

Before any steps are taken toward any level of intervention, school counselors must first "look in the mirror," and begin with their own personal development. School counselors must develop multicultural awareness and competence in order to provide effective and relevant educational experiences for all students. The first stage of multicultural competence is self-awareness. Awareness of self includes introspection of one's own thoughts and feelings regarding culture (Fusick & Charkow Bordeau, 2004). Self-introspection involves gaining an awareness and understanding

of the values, behaviors, and beliefs of one's various reference group memberships (e.g., race, ethnicity, gender, social class, sexual orientation), and how these affect one's interactions in the world. This is a vital process before one begins to try to understand others. Without awareness of self, counselors may unknowingly discount or dismiss cultural influences and differences among the students they serve, and subconsciously believe they understand the culturally different when, in fact, they view others from their own cultural lens, which may cause certain things to be taken for granted (Locke, 2003). Counselors need to remember that they bring their own cultural worldview to their interactions with students, and their perspectives and experiences are not mutually exclusive to everyone else.

Counselors need to explore other cultures and the worldviews of others as well. School counselors need to understand and accept the worldviews of others in a nonjudgmental manner in order to work effectively with all students. This is particularly important in urban settings where there is increasing cultural diversity, and counseling interventions are continuously impacted by language issues and cultural differences (Lee, 2005). School counselors need to acquire practical knowledge about a student's cultural background and daily living experiences (Sue & Sue, 2003). However, one must be careful not to overgeneralize things learned about other cultures as applicable to all members of that population. Cultural group membership does not mean that people are not individuals with uniqueness or differences. All students must be seen as both individuals *and* members of their particular cultural groups (Locke, 2003).

Counseling Services—Individual

With a greater understanding of one's own cultural awareness and of others, school counselors can provide effective individual counseling services to students. The school counselor is often the first line of defense to identify critical issues occurring with the student, as well as to intervene in crisis situations. School counselors can provide short-term counseling as well as referral to community mental health resources. This is particularly important for children and families who do not have the financial resources or insurance benefits to support mental health services outside of schools (Romano & Kachgal, 2004).

Counseling Services—Group

While there are clear benefits to offering individual counseling, it is not always financially feasible, practical, or even culturally appropriate for many students (Yeh, 2004). Therefore, school counselors may need to reduce the amount of time in individual counseling with students and work toward serving larger groups of students. Working with students in groups may provide opportunities for doing outreach, developing and implementing programs that effectively deliver preventive interventions to larger numbers of students, and encouraging students to learn from each other (Yeh). For example, elementary and/or middle school counselors can offer direct instruction in social skills to groups of students in the classroom as an intervention, especially when social isolation and feelings of rejection have been found to contribute to a student's performance. This is most appropriate for students at these earlier stages of development. In addition, there may be more classroom time available for counselors to run psycho-educational groups, as there are fewer requirements for graduation for students at these levels.

Parent/Family Level

Difficulties that begin in the home often manifest themselves within the school setting (Abrams et al., 2005), and counselors need to be at the forefront for identifying those students with familial stressors. This may involve counselors stepping outside of their office from their traditional role and becoming advocates and liaisons for students (J. J. McWhirter, 1998). School counselors can explore the chaos, pressure, and stress that may result from multiple activities and demands on the lives of parents and/or caretakers that may be contributing to the students' school performance. As an advocate, the school counselor identifies a need that is not being met or a past injustice that has not being corrected by the school and speaks for or in support of the student and/or family in requesting a needed service (Juntunen, Atkinson, & Tierney, 2003).

As a liaison, school counselors can advocate for appropriate social services for students and their parents. This is especially pertinent for students living in poverty, usually in urban and rural areas (approximately 22% to 24% of urban and rural children live in poverty; Hines, 2002). Concentrated poverty heightens the probability that school children will lack access to regular medical care, have a parent who never finished high school, become pregnant, or drop out (Lee, 2005). Medical and mental health services are limited and community services are usually fragmented in high poverty areas, and the school counselor can facilitate access to information for students and parents and serve as a liaison or mediator among student, parents, the school, and other agencies (Locke, 2003).

It is clearly important for school counselors to have good working relationships with the families of their students. In general, it is essential to make every effort to involve parents and other caregivers in the academic lives of youth. Adults were found to exert a large influence on

the behaviors that bolster mental health among marginalized youth. Although peers are increasingly more important during adolescence, all children and adolescents remain attached to parents even as they expand their networks of associations (Estell, Farmer, Cairns, & Cairns, 2002). School counselors can help parents structure their worlds and offer a support network so that the school tasks students need to accomplish are achievable (Ungar, 2004). As an intervention, counselors can suggest to parents to make time to talk and listen to their children. This simple intervention requires no additional financial resources or funds and can increase quality time spent between children and their parents, increase parental awareness of their child's behaviors and opinions, and improve their relationships (Abrams et al., 2005).

School Level

Schoolwide Prevention/Intervention Program Development

In general, successful intervention and/or prevention programs to address school failure need to be comprehensive, interfacing family, school, and community efforts rather than offering a single, narrow intervention in one environment (McCluskey et al., 2004). Programs should be implemented over time and have a longitudinal focus, rather than focusing on a single period in time. Change to reverse school failure should be considered in terms of years rather than weeks, especially since most types of failure among children and adolescents are the result of a long process of disengagement (McEvoy & Welker, 2000).

School counselors may also need to be creative with their interventions and not stress the school faculty and its resources. In school settings, such as urban and rural schools, there are often fewer resources and less money to spend per student, as well as less access to educational technology, and greater teacher and administrator shortages (Hines, 2002; Lee, 2005). Counselors may need to stretch funding and find alternative ways to pay for programs.

Interventions should be tailored to fit individual students' needs, rather than adopting a programmatic "one-size-fits-all" orientation. All attempts should be made to personalize education for students. Counselors should strive to understand the nature of academic, social, and personal problems affecting students and tailor services to address students' individualized concerns (Christenson & Thurlow, 2004).

Programs should also do more than focus on increasing student productivity. They should help students and families who feel marginalized in their relations with teachers and peers feel connected to school and with learning. Student engagement across the school years depends on the degree to which there is a match between the student's characteristics and the school environment, so that the student is able to handle the academic and behavioral demands of school. Effective programs should focus on building and fostering positive relationships between students and those who will be supportive to them (e.g., teachers, parents, and peers), as well working on developing students' academic skills (Christenson & Thurlow, 2004).

Additional Points to Consider

Identify risk factors early. Identifying factors that interfere with academic success is a crucial first step in the process of choosing interventions to address this issue, and the best way to gain an accurate picture of interfering factors is the use of data. Concrete information about which students are failing (e.g., failing specific classes, increased absenteeism rates, etc.) can give counselors valuable knowledge to advocate for programs and polices that will be effective (Dimmitt, 2003). School counselors can build a database that provides them with information about the most salient factors for their population and continue to collect data consistently to identify problems within their system (Dimmitt).

For example, school districts could examine patterns of absenteeism within their school to identify youths at risk for dropout and to design subsequent preventive programs. Factors to consider may be number, frequency, and types of absences. Child reports are particularly important to understanding concerns in specific classes. Also as part of the data collection, consideration must be given to whether a child's absenteeism is primarily related to parental factors, such as illness, pregnancy, homelessness, or maltreatment. All of this data and information can be obtained from a combination of child, parent, teacher, and school attendance reports (Kearney, 2003).

School counselors can build collaborations and research partnerships between school counseling programs and counselor education programs at the university and graduate levels to assist them with data collection and research efforts within their school. These collaborations can provide needed resources and information for all involved. For the counselor already working in schools, partnerships with graduate students can provide assistance with research information and data analysis. In exchange, school counselors can provide useful educational experiences for graduate students who will learn more about the interplay of theory and practice in school counseling (Dimmitt, 2003).

Try to get all school faculty and staff involved. Within school, children and adolescents interact with and are impacted

by a variety of school personnel, and as such, everyone within the school has a considerable impact on the students' educational success. It is important to try to gain an atmosphere of collegiality and collaboration so all within the school who are expected to implement new systems of change feel as though they have been given a voice in their design and can begin to "buy in" or gain a vested interest in the effort to ensure its success. Because time is a scarce resource, potentially successful interventions will receive little support if school personnel consider them to be too labor intensive. Often, intervention efforts fail because they are imposed from the top down as an additional responsibility. School counselors can use their group dynamic skills and training to bring together a team of individuals who are willing to work together, and then be leaders of the group to facilitate the intervention process (Abrams et al., 2005).

Moreover, school counselors can offer workshops to educate and inform other school personnel about the needs of the student population. If programs will be developed to "add on" responsibilities for teachers and other staff, there is a need for proper training and staff development opportunities. For example, counselors can act as consultants creating workshops to discuss curricular changes to make content more relevant to students' needs. Moreover, counselors can have discussions with teachers about multiple learning styles, the use of multimodal teaching methods, and/or multiple types of assessment to share information about differing student learning styles based on cultural background and differences (J. J. McWhirter., 1998).

Establish a coherent and clear framework for programs. In the absence of a clear rationale, many school-based programs for students who fail may be constructed in a seemingly random and inconsistent manner (McEvoy & Welker, 2000). Schools with mission statements, comprehensive curriculum plans, schoolwide assessments, and coordinated intervention programs are more likely to have greater success (Dimmitt, 2003).

Emphasize students' strengths instead of deficits. All school personnel must emphasize the development of students' competencies rather than dwelling on their deficits (Christenson & Thurlow, 2004). School counselors' and teachers' beliefs and attitudes about students have considerable impact on the educational process. When significant adults believe that their students are competent and capable, those students are more likely to be successful (Dimmitt, 2003).

Continue to have ongoing assessments of programs. Ongoing assessments of implemented programs are necessary to evaluate their effectiveness within the school and with its students. As the school's climate changes and programs are implemented, there may be a need to add or delete aspects of the program. This requires the school to have in place a system for monitoring students' changes and goals, which can be led by school counselors (McEvoy & Welker, 2000).

Case Examples

Brooks-McNamara and Pederson (2006) illustrated an excellent real-life example of a systemic intervention program initiated by a school counselor, created from an ecological theoretical conceptualization. An elementary school counselor observed that a high percentage of third-grade students were failing state standardized tests. This spurned a further, more detailed investigation of this third-grade "low-scoring" cohort. An examination of several factors, including student family background profiles, revealed that most of the students in this cohort came from single-parent, low-income families in the same apartment complex. This was the beginning of the development of a powerful intervention program at this school. Strategic planning teams were developed that resulted in the following intervention. In school, strategies for supplemental help in reading, writing, and math were created. In addition, middle and high school students were recruited from the district as peer tutors. (These students also lived near if not within the same apartment complex as most of the third-grade students.) The counselor was able to recruit educators to conduct parent workshops for encouraging and supporting academic achievement at home, using the resources available to them. After the initial development of the program, a 2-year post follow-up review was conducted. One new strategy was developed. Some of the parents developed an agreement for release of information between the school and the "Homework Club" personnel. (These were the peer tutors and teachers who were involved in tutoring the students.) Once this agreement was signed, the school was able to discuss and assist with monitoring student progress without having to first consult with the parent. This was an effective new strategy as many parents were not able, due to conflicting work schedules, to be as directly involved in the program. However, their children were not sacrificed, rather communal efforts helped to maintain their academic progress. The school counselor continued to track the overall achievement of the cohort of students. Results indicated that the intervention was a success; 88% of the third-grade students passed the reading exam, and 86% passed the math!

Another fascinating, effective example of an intervention program for school failure utilizing a group approach is EGAS (empowerment groups for academic success; Bemak,

Chi-Ying Chung, & Siroskey-Sabdo, 2005). This program was developed by the principal author, who worked closely with a school counselor in an urban Midwestern school identified as having students at the highest level of risk for school failure. This school experienced high rates of expulsion and suspension, academic failure, absenteeism, and school dropout. The goal of the program was to assist in resolving the difficult personal and interpersonal issues faced by high-risk students, as a means of improving academic performance and attendance. The program took a group approach, and its members were composed of 7 African American girls in the 10th grade, all of whom were identified by counselors, teachers, and administrators, as being at the highest level of risk, and who had been involved in previous failed school interventions. The key element to the EGAS approach is that it emphasizes empowerment through group process, moving away from the traditional structured group format. Group members controlled the group so that true empowerment resulted as members had an actual say in how the group was run, instead of a "facilitator" determining what was important and relevant to discuss. The group decided on a weekly agenda, meeting once a week for 45 minutes during school hours. Topics of discussion included family and peer relationships, death of friends and loved ones, pregnancy and single parenting, experiences with first sexual encounters, smoking, confrontations and poor relationships with teachers, and general school and academic concerns. Interestingly, the group felt that it was able to reenact a "family" through its members, providing support, which is an important and necessary aspect of healing, as well as a crucial factor to promote future school success. Moreover, through the exploration of real-life issues and struggles the group members faced, for the first time group members were able to examine the relevance and the relationship between these factors and their school performance. As a result of their participation in this group, marked academic improvements were evident in the group members.

On a more individualistic perspective, TeamMates is another example of an intervention program working with school failure. Dappen and Isernhagen (2006) studied this Midwestern, statewide, school-based, one-to-one mentoring program. TeamMates was initiated formally in 1991 by a football coach at a state university. He asked his players to volunteer to mentor local youth. During the first year, 25 student athletes volunteered to mentor seventh- and eighth-grade students in an urban school district. The program slowly grew, and by 2000, there were 1,490 students and mentors in the program. The TeamMates structure includes a state advisory board, executive director, and four regional coordinators who work with different districts. The state offices provide technical assistance for operation of the mentorship program. The mentors meet once a week with students during school time. The primary task of the mentor is to establish a positive, personal relationship with the student and assist him or her in any way possible. The program works with students beginning in early middle school through high school, with the goal of post secondary education. Although this particular program was not initiated by a school counselor, school counselors can follow this successful model and work to incorporate similar programs within their school districts.

Community/Societal Level

One must acknowledge that schools were created and designed to meet the needs of the dominant group (i.e., White American middle class); however, with the changing demographics of America's school children (currently almost 40% of the total public school population is students of color; U.S. Department of Health & Human Services, 2001), changes need to be made to the structure of the school system (J. J. McWhirter, 1998). Societal injustices, such as racism, are all aspects of a culture that must be understood and examined as a part of one's personal belief system, as well as a part of the larger culture in which one functions (Sue & Sue, 2003). Social injustices can be seen in the attitudes and beliefs of the school system in which the counselor works, and the counselor may be supporting these attitudes solely on the basis of participation in his or her school (Locke, 2003). For example, in the past 10 years, the majority of states have adopted statewide student assessment systems (usually in the form of testing), based upon standard state curricula. State policy makers believe that setting high standards will improve the state of education in the United States and decrease school failure. Because the tests are intended to communicate high expectations, all students in the state are required to pass the same test. However, according to the NAEP in 2003, White students outperformed racial/ethnic minorities in almost all subjects (USDE, NCES, 2005), and dropout rates are disproportionately high for students of color (approximately 50%). Are these high-stakes testing reforms serving to improve the educational achievement of everyone or is this another method to marginalize groups that are already culturally, racially, and linguistically disadvantaged?

As agents of systemic change, school counselors can be involved in educational reform efforts. First and foremost, though, school counselors must understand the system and learn how the system works. The chances for success increase if one consults first, rather than intruding and demanding change (Baker, 2000). Moreover, the school counselor who works as an agent for social change must be realistic when supporting the causes of inequity,

injustice, and unfair practices within a school and advocating for promoting educational equity for all students. It is essential for school counselors to have the skills and support to balance the institutional realities of working within systems where they may have minimal power (Bemak et al., 2005). They can begin by soliciting community support. Most communities have a wide range of resources including medical professionals, social workers, or spiritual leaders, who together can exert power and pressure to effect change once they are informed of the issue via the school counselor. In particular, within communities of color and in rural communities, school counselors can tap into the inherent support and power within the community to help elicit change (Hines, 2002).

On an individual level, school counselors may serve on school curriculum committees to advocate for changes that address the educational needs of students, such as selecting culturally relevant educational materials (Romano & Kachgal, 2004).

It is important to note that school counselors who accept the challenge to be social change agents should be realistic with their efforts and not try to be martyrs. Counselors need to be careful and protect themselves from burnout; otherwise they will be used up by the same systems they are trying to help their students understand and manage (Baker, 2000).

Summary and Implications

School failure is a pervasive problem that continues to persist in our society in multiple forms. This chapter sought to examine the multiple degrees of school failure beginning with academic failure, which is generally the precursor to more serious levels of school failure, to truancy, grade retention, and most severe, dropout. In general, most understand the problem of school failure as an individual consequence to negative behaviors, and as such, plan interventions based on this individualistic perspective. However, from an ecological perspective, school failure can be understood as a cumulative result of multiple layers of influence on a child's performance, including their family, school, and communal environments. From this broader perspective, one can better identify the stressors (beyond the individual) that impact the student and identify multiple possibilities and ways to respond, intervene, and affect lasting change. The school counselor plays a critical role in helping students and schools address major issues that affect learning and academic achievement. School counselors should expand their role beyond "counselor," to act as consultants, advocates, and social change agents to attend to the full development of students, offering a range of services that include individual and small-group counseling, psycho-educational classroom activities, and consultation with teachers, parents, and community agencies. An ecological approach offers school counselors a useful framework for identifying appropriate interventions in their work with students whose behaviors fit along the school failure continuum.

American society is plagued with rampant social issues that affect students attending school and result in school failure for some. School counselors are in a position in which they cannot ignore these issues and are called upon to intervene with students in ways that may be intimidating, overwhelming, and unfamiliar. Although the training and practice of school counselors has experienced renewed attention in recent years, all training programs need to expand their programs and develop trainees to take on broader roles in their professional identity as school counselors. Training programs need to expose their students to a variety of roles outside the traditional counselor role, such as advocate, consultant, and social-change agent, and help trainees to understand how they can incorporate these identities into the political–social system of the school. Moreover, training programs need to infuse their curriculum with diversity and train students to be more multiculturally competent, especially since our school-aged population is becoming increasingly more racially and ethnically diverse, and these students have been found to be the most vulnerable to school failure.

XXXIX
MEASURING AND EVALUATING ADOLESCENT CONNECTEDNESS

MICHAEL J. KARCHER, MICHELLE R. HOLCOMB, AND ELIAS ZAMBRANO

University of Texas at San Antonio

Introduction

School counselors who can demonstrate that their guidance and counseling programs result in improvements in their students' connectedness to school, teachers, and peers are less likely to be pulled in 100 different directions by administrators, teachers, and parents. Based on our experiences, we argue that this is because such counselors are viewed as providing unique and highly valued services. However, school counselors who utilize a comprehensive and organized approach to deliver guidance presentations, individual student planning, system support, and responsive services (American School Counselor Association [ASCA], 2003), and who can demonstrate that this coordinated set of services results in improved connectedness among their students are less likely to be asked (or expected) to engage in nonguidance activities, such as supervising testing, scheduling classes, or supervising lunch. Or, if asked, these counselors can point to their impressive body of evaluative evidence. They can use it to define the borders of their professional duties and, thereby, educate parents and colleagues alike about the unique and valuable role that professional counselors play in schools.

It is, therefore, incumbent upon school counselors to create and organize a quality program that is amenable to evaluation in order to demonstrate accountability. The planning of such thoughtful, focused, and intentional services takes time, but also requires forethought in order to anticipate desired outcomes that, from the outset, are measurable. Compounding these time constraints on program planning, many school counselors may believe they have limited training or insufficient tools at hand to link their program component's activities to program outcomes.

This chapter provides a guide to help school counselors to both systematically assess and strengthen the impact of their school counseling programs by focusing on promoting changes in students' connectedness. The theory of adolescent *connectedness* (Karcher, 2001) presented in this chapter defines connectedness as movement toward others through positive affect and activity. Connectedness is reflected in a student's response to feelings of relatedness and belonging. This definition provides the first key to intervention: To promote connectedness, school counselors must create school contexts where youth feel a sense of belongingness at school and relatedness to teachers and peers. When youth feel a sense of relatedness and belonging, they typically value those relationships and social institutions in which they experience the belongingness and relatedness. But school counselors then must help students pursue related activities and relationships which cement their connections through behavioral and affective commitment. Finally, connectedness can be captured in adolescents' own perceptions of their own involvement in and affection for others, activities, and organizations. Given this, connectedness is measurable and can be used as an indicator of program outcomes.

Of course, connectedness is but one outcome or construct a school counselor might wish to measure as evidence of outcomes. Other important constructs include social skills, self-esteem, peer attachment, cultural competence, and other behavioral and attitudinal indices of social competence and a positive orientation to school. For the purposes of this chapter, connectedness is solely emphasized in order to provide a comprehensive overview of one measure, its uses and evaluative procedures, which we believe will allow the reader to make generalizations and comparisons with other measures.

The Problem—Capturing the Effects of School Counseling Programs

The notion of connectedness has become increasingly popular in the media as well as in academic and educational settings (Lezin, Rolleri, Bean, & Taylor, 2004; Resnick, Harris, & Blum, 1993). The construct of connectedness is viewed by many as increasingly important in a mobilized, postindustrialized, multicultural, and technologically alienating society, such as is found in the United States. Children and adolescents need healthy connectedness to family, siblings, friends, and eventually romantic partners in order to weave themselves tightly into a supportive social network. Connectedness to school, teachers, and peers during the middle and high school years is a particularly strong predictor of academic and future success, but it also helps to prevent alienation, which can lead to violence such as that of the Columbine massacre; the Washington, DC, shootings; or the countless other acts of desperation performed by students in recent years (Henrich, Brookmeyer, & Shahar, 2005; Karcher, 2002). Adolescents also need to learn to effectively connect with culturally different peers, the world of reading, a source of spirituality (regardless of persuasion, denomination, or creed), and their neighborhoods. Because parents and researchers alike recognize the ubiquitous necessity of connectedness, it is important for school counselors to know how they can promote and measure connectedness.

Using Connectedness to Capture, Profile, and Predict Developmental Assets

The *Measure of Adolescent Connectedness* described in this chapter had direct parallels to the Developmental Assets presented by the SEARCH Institute. The 40 Assets listed in the SEARCH framework focus the attention of school counselors, teachers, parents, and youth on the positive relationships, opportunities, skills, and values that can support the healthy growth and development of youth (Scales & Leffert, 1999). The model asserts that the more young people experience these 40 Developmental Assets, the more likely they are to engage in prosocial behaviors and conversely, the less likely they are to participate in harmful behaviors (Benson, Galbraith, & Espeland, 1995). Using data collected with the SEARCH Developmental Assets survey, we refer to key assets in later sections to illustrate ways in which the measure of adolescent connectedness can serve as a proxy measure of assets and can thereby be used to facilitate and extend the use of the Developmental Assets framework.

The SEARCH Institute's Developmental Assets constructs have become a central organizational framework for many school districts, helping school counselors organize efforts to promote external and internal assets among students (Scales, 2005). Numerous school districts have used the SEARCH Institute's Developmental Assets framework to make fundamental changes in the structure of their schools and to improve students' relationships with teachers and peers. In addition, statewide initiatives, such as California's Proposition 49, actually require that school connectedness be assessed, in addition to other constructs currently informing guidance programming in schools. The *Measure of Adolescent Connectedness* can be used to supplement and extend the Developmental Assets framework by linking guidance program content with measurable outcomes. We argue that using the connectedness construct and measure described in this chapter may make the asset-promoting activities they propose even more useful in guidance programming.

Finally, our approach is based on the authors' combined experiences of conducting research on connectedness and our firsthand experience as school counselors and the director of school guidance programming for a large urban school district that used the SEARCH Developmental Assets framework as its organizing framework. Based on these experiences, we focus on illustrating ways to track changes in connectedness that result from guidance programming within the schools. In order to help the reader better understand how to assess connectedness among middle and high school–aged students, we present a theory of adolescent connectedness, describe *The Hemingway*: *Measure of Adolescent Connectedness*, provide normative data for one district and new research on connectedness, and finally bring this theory and research to practice by describing several strategies for developing a program of services that carefully links evaluation with efforts to promote assets and connectedness as part of a comprehensive guidance program.

Theory

Connectedness has been described as one of the five "Cs" that Lerner, Fisher, and Weinberg (2000) suggested youth development programs must target. This is due, in part, to its usefulness as a predictor of a number of developmental competencies as well as risk behaviors. However, while to date no theoretically derived measure of adolescent connectedness has been empirically tested for use in schools, adolescent connectedness has landed squarely in the middle of the emerging field of applied youth development (Roth & Brooks-Gunn, 2003). For example, in their review, Roth and Brooks-Gunn found that all of the youth development programs they reviewed attempted to promote one or more forms of connectedness. Of these programs, 73% explicitly "sought to improve adolescents' connections; connections with their families (40%) and peers (42%) were the most common connection goals for

the programs" (p. 207). Yet, only half of those programs designed to promote connectedness actually used a measure of connectedness to evaluate program success. "More programs held goals of promoting . . . connections than actually measured these characteristics in the evaluations. Of 35 programs promoting connectedness only 19 (54%) reported measures of connectedness" (p. 215).

The absence of a measure of adolescent connectedness and definitional framework presents a huge barrier to fully exploiting the usefulness of the connectedness construct as a target of school counseling programs. Adolescent connectedness must be clearly defined and reliably measurable before research can have a positive influence on the field of school counseling and the applied developmental sciences. Measures used in most studies have been ad hoc, and when described within each study, the term *connectedness* often has been used interchangeably with other words such as *bonding*, *attachment*, *belongingness*, and *relatedness*. Not until a clear nomenclature for connectedness is established and measures of connectedness receive sufficient validity evidence will this, the third of the five Cs of applied youth development programs, be a useful and meaningful target for programmatic influences of school counseling on youths' developmental competencies.

The Ecology of Adolescent Connectedness

The model of connectedness presented in this chapter is derived from ecological and developmental theory. From these perspectives each world of the adolescent's social ecology—school, friends, family, and neighborhood—can be viewed as a world of connectedness. Used in this way, the term *world* refers to common and important contexts, relationships, and activities of engagement in the lives of adolescents (Nakkula & Selman, 1991).

The concept of *connectedness* has sometimes been restricted to participation or involvement in interpersonal relationships (Gilligan, 1991; Jordan, Kaplan, Miller, Stiver, & Surrey, 1991), but this definition is needlessly restrictive and inconsistent with the public's broader use of the term, which is more ecological in nature. Broadly defined, connectedness includes the acts of giving back to, being involved with, and investing oneself in an affective manner in places and activities as well as in relationships with other people. "Connectedness occurs when a person is actively involved with another person, object, group or environment, and that involvement promotes a sense of comfort, well-being, and anxiety-reduction" (Hagerty, Lynch-Sauer, Patusky, & Bouwsema, 1993, p. 293). Connectedness is not restricted to relationships. For example, youth can be connected to school and to reading just as they may care for, enjoy, and be actively involved with a teacher, peer, friend, or parent.

We suggest that there is a connectedness to self, which emerges during adolescence as a sense of self that is influenced by unique relationships with family memberships, teachers, and friends (Erikson, 1950; DuBois, Felner, Brand, & Phillips, 1996). Adolescents' self-esteem in these contexts informs a connectedness to self that is primarily present oriented. In addition, the ability to think abstractly results in the differentiation of a *present self* and from a *future self* (Harter, 1999). Because youth can have feelings about and engage in activities directed toward each of these selves, we include them as well.

The ecology of adolescent connectedness includes all of the significant ecological systems (e.g., micro-, macro-, and meso-) that adolescents experience in their day-to-day lives (Bronfenbrenner, 1979). Microsystems include youths' important relationships at home with parents and siblings, in school with teachers and peers, and in youths' neighborhoods with friends. Macrosystems of connectedness are the larger institutions in youths' lives in which these microsystemic relationships and activities occur and include one's neighborhood, family, school, religion, and cultural group. The mesosystems are those processes of connection that link micro- and macrosystems. For example, reading is one main mesosystem that links the home and school by orienting interpersonal connections. Reading is an activity that links the youth to school, teachers, and friends. Adolescent connectedness generalizes beyond immediate dyadic relationships (or microsystems) toward activities associated with these contexts, such as reading. In principle, using this same logic, one could suggest that smoking, drinking, and fighting (as something youth may participate in with friends) are mesosystems as well, but we restrict the term connectedness to types of affective and behavioral engagements that are (at least potentially) catalysts for positive youth development. And although connectedness to one's friends and neighborhood can contribute to risk-taking behaviors, a sufficient degree of connectedness to friends and one's neighborhood environment is essential to positive youth development. By comparison, because smoking and drinking do not provide a similar protective function for youth, they are not forms of connectedness included in our conceptualization.

The Continuum From Conventional to Unconventional Connectedness

Each of these worlds of connectedness can be characterized as falling somewhere along a continuum of conventionality. This concept of *conventionality* was initially proposed and described by R. Jessor and S. L. Jessor (1977), and it is used here as it is defined in *The Oxford Compact English Dictionary*: *Convention* refers to the "way in which some-

thing is usually done" and "socially acceptable behaviors" (Soanes, 2003, p. 234). *Conventional* means "following social convention; not individual or adventurous" (p. 234), where the conventions are those behavioral prescriptions set by adult society. Connectedness, then, can be characterized as either conventional (adult sanctioned) or unconventional (youth sanctioned).

Highly conventional worlds include those contexts, relationships, and activities that are structured, sanctioned, and supervised by adults. These conventional worlds of connectedness are antithetical to problem behaviors and risk taking (Donovan, Jessor, & Costa, 1988). Conventional connectedness typically includes the social worlds of school, teachers, reading, religion, and family—all of which are structured by adults and directed toward the future. Positive orientations toward and active involvement in all of these worlds serve to buffer against violence (Honora & Rolle, 2002; O'Donnell, Hawkins, & Abbott, 1995).

Conversely, connectedness to peers, friends, and the neighborhood may be conventional if the nature of these relationships and activities reflects attitudes and conventions prescribed by adults. However, this tends not to be the case for many youth (Karcher, 2001). Due to its customarily unsupervised nature, connectedness to neighborhoods and time spent with peers, friends, romantic partners, and (for some) siblings is primarily unconventional. Being antithetical to adult conventions, unconventional connectedness often elicits activities that may lead to problem behaviors. The *un*conventional worlds of connectedness are those social ecologies in which youth themselves typically dictate the norms, activities, and structures that govern or dictate appropriate interaction. Youths' neighborhoods (for early adolescents), friendships, and romantic relationships (for older adolescents) are the most common examples of contexts/relationships in which unconventional connectedness develops and directs behaviors.

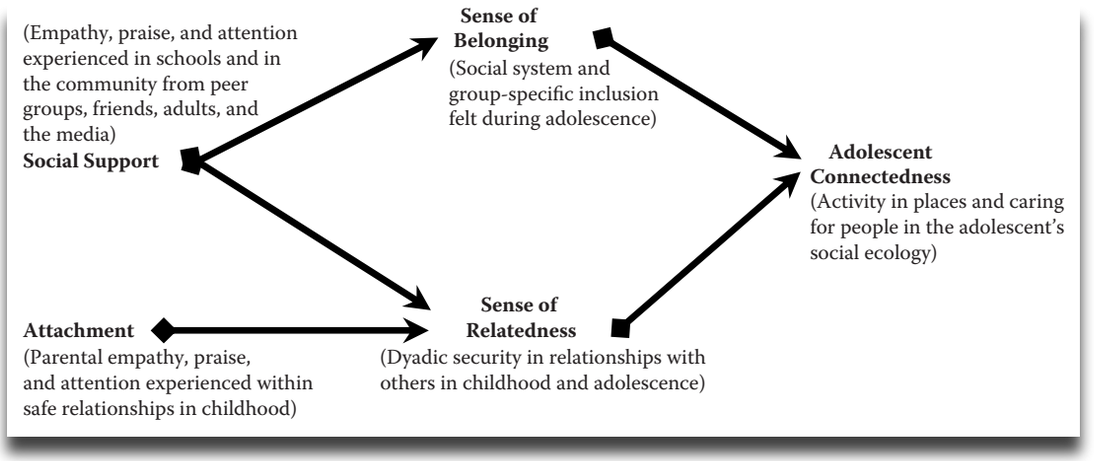
All adolescents need to achieve a minimum amount of connectedness across their social ecology and in both conventional and unconventional worlds. Problems typically emerge for those youth who are not able to establish sufficient connectedness within the family, school, and other conventional contexts, relationships, and activities (e.g., reading). Youth at risk for academic underachievement often establish an imbalance, engaging in more unconventional than conventional connectedness.

Promoting connectedness in the school setting can serve to counterbalance the increasing importance of connectedness to peers, friends, and romantic partners during adolescence by providing an opportunity for conventionally disconnected youth to form connections with more conventional peers and adults at school. Youth whose primary affections and engagement are with peers and friends engage in more unconventional, illicit behaviors and are more likely to denounce school and other conventional contexts and relationships. In contrast, youth who are actively involved in, enjoy, and feel positive about school are less likely to engage in violent behavior, substance use, and other related problems that interfere with academic success (Cernkovich & Giordana, 1992; Farrington, 1991; O'Donnell et al., 1995; Olin, 2001). For this reason, promoting active engagement in school and positive feelings about school (viz., connectedness to school) should be at least one of the primary targets of school-based violence prevention programs. Promoting connectedness to friends who engage more in conventional, prosocial behaviors, such as by encouraging students to participate in extracurricular activities, clubs, and organizations where friendships grow in the context of conventional activities should be another target of programs.

The Developmental Origins of Adolescent Connectedness

Connectedness has several likely precursors, including attachment to caregivers, relatedness to others, and feelings of belongingness within social groups. Karcher (2004) proposed that connectedness develops in reaction to (a) attachment, (b) interpersonal social support, and (c) group-level experiences of belonging (see Figure 39.1). We define *connectedness* as youth's active involvement and caring for other people, places, and activities. Connectedness is the reciprocation of the support and positive affect that other people have provided youth in specific places. This reciprocal process reveals an opportunity for structuring programs and experiences in schools that aim to promote connectedness.

Connectedness is not a feeling of belonging or relatedness; rather connectedness reflects an extension and reciprocation of basic attachment and bonding processes into the adolescents' widening social ecology. As with indicators of attachment, connectedness reflects proximity seeking (i.e., movement toward) and positive affect for people, places, and activities in the adolescent's life. This is an important definitional distinction. Connectedness is not a bond that is felt, but a volitional, active "bonding" with other people, places, and activities. In this way, promoting connectedness in schools means not *only* "helping students feel supported" but *also* creating supportive conditions, such as through group work, activities, and collaborative learning, which act to foster connections in the form of action-based, attitude-driven involvement in school.



(Empathy, praise, and attention experienced in schools and in the community from peer groups, friends, adults, and the media)
Social Support
Sense of Belonging
(Social system and group-specific inclusion felt during adolescence)
Adolescent Connectedness
(Activity in places and caring for people in the adolescent's social ecology)
Attachment
(Parental empathy, praise, and attention experienced within safe relationships in childhood)
Sense of Relatedness
(Dyadic security in relationships with others in childhood and adolescence)

Figure 39.1 A hypothesized model of how attachment, social support, relatedness, and belonging contribute to adolescent connectedness.

Connectedness: The Reciprocation of Belonging, Relatedness, and Attachment

Connectedness has, as its source, positive relationships and experiences with others, and more specifically, relationships and experiences from which youth garner esteem and competence. Ideally, early in life, primary experiences of relatedness with caregivers result in positive attachments with caregivers and provide children with their initial sources of support, esteem, and praise (Ainsworth, 1989; Kohut, 1977). Later, other forms of social support build upon these early experiences, and provide interpersonal relatedness outside the family (e.g., teachers, peers, and friends) and experiences of group belonging beyond the family (see Figure 39.1). These socially supportive interactions usually result in positive feelings of relatedness and belonging. Youth reciprocate these feelings and "connect" with others by assigning them positive affect and seeking continued interaction with them (Baumeister & Leary, 1995). This reciprocation is similar to that of plugging in a power cord whereby one actively seeks out the source of connectedness (relatedness and belonging). Connectedness is not synonymous with relatedness and belonging; connectedness is a behavioral and attitudinal response to those feelings.

Attachment. Connectedness is present early in life in the caregiver–child bond. Attachment reflects the behavioral reciprocation of affective experiences by the child to the caregiver through proximity seeking and positive affect (Chodorow, 1978; Stern, 1985). Like the toddler, the adolescent becomes connected to those social worlds that provide the adolescent the basic interpersonal ingredients of development—empathy, praise, and attention within relationships in which they receive clear, consistent structure (Ainsworth, 1989; Kohut, 1977; Kohut & Elson, 1987). Likewise, adolescents report positive affect and demonstrate proximity seeking most strongly toward those people—parents, siblings, peers, friends, or teachers—who have provided them with empathy, praise, and attention in a clear and consistent manner.

This is key to intervention and may explain why these qualities have been found in the most effective prevention programs (Catalano, Berglund, Ryan, Lonczak, & Hawkins, 2002; Schorr, 1988). Arguably, no amount of skills training or heightened knowledge will effectively curb risk taking among youth if such interventions are devoid of positive interpersonal relationships in which youth can feel competent, understood, and important.

Social support. Past and present levels of social support will affect youths' receptivity to interpersonal interventions. There is evidence that early attachment experiences predict individuals' openness to receiving help and willingness to accept social support during adolescence. For example, Mallinckrodt (1991) found that the quality of late adolescents' relationships with their families and with important nonfamily members was a significant predictor of the quality of their therapeutic working alliance. The author argued, "[T]he ability to meaningfully connect with others is presumed to be a good indicator of their capacity to form productive working alliances" (p. 402). Therefore, adolescents' ability to benefit from social support will be constrained by the quality of their experiences with other people (Lee & Davis, 2000), such that those who have received the least social support in the past may be the hardest to reach by school counselors. Indeed, others have found that aggressive youth who overestimate their social relatedness (and report excessively high self-esteem) can be the most difficult to reach through interventions (Prasad-Gaur, Hughes, & Cavell, 2001). Relatedness and belonging are two indicators of how open youth may be to receiving social support from others.

Relatedness. Relatedness is the felt sense of closeness and of being valued by another individual. Relatedness is determined, in part, by the security youth experienced in early caregiver–child relationships, and relatedness predicts the degree to which youth will seek interpersonal connection in later relationships with peers, friends, and teachers (Kuperminc, Blatt, & Leadbeater, 1997). Hagerty et al. (1993) suggested that relatedness is a "functional, behavioral system rooted in early attachment behaviors and patterns," such that "affiliation or exploration are activated only after the attachment behavioral system" (p. 292). Breaks in relatedness, such as through forced separations, undermine connectedness by lessening youths' willingness to invest time and energy in relationships with others (Kuperminc et al., 1997; Richters & Martinez, 1993). For example, Midgley, Feldlauffer, and Eccles (1989) reported that students who moved from elementary classrooms where they experienced high teacher support to middle school classrooms where they perceived less teacher support showed decreases in their interest in learning. In short, undermined relatedness creates a lapse in connectedness. When teachers do not provide consistent sources of empathy, praise, and attention, as well as a clear, consistent structure, youth will become less involved in school and will become less inclined to establish conventional school-based relationships (van Aken & Asendorpf, 1997).

Belonging. When relatedness occurs in groups of people or in defined contexts, the result is the experience of belonging. Belonging is of paramount importance to adolescents. *The need to belong* is defined, not as the need to be the passive recipient of supportive relationships, but as the need for "frequent [positive and pleasing] interaction plus persistent caring" (Baumeister & Leary, 1995). Hagerty et al. (1993) described connectedness to others, as well as to organizations and their activities, as a reciprocation of experienced belonging and relatedness that has, directly or indirectly, primary attachment relationships at its source. How accepted and valued a youth feels by a particular group shapes how connected, involved, and concerned that youth will be with people and activities in that organization. This is because youth confirm and acknowledge their experience of belonging by becoming connected through increased interaction and caring for other people and places (see Figure 39.1).

Defined from an ecological point of view, then, adolescent connectedness reflects a youth's volitional involvement in relationships, contexts, and activities that he or she deems positive, worthwhile, and important. As a reciprocation of one's positive experiences of relatedness and belonging with others in particular places, connectedness is a function of the social support presented to individuals, his or her openness to receiving that social support, and security in those relationships and contexts. School staff and peers can vary the social support they provide to students; however, they cannot as easily change students' openness to receiving that social support. Receptivity to social support is partly driven by prior experiences with others, including early interactions with caregivers. In addition, openness to social support is influenced by recent and current experiences both of inclusion with or exclusion from groups and teams as well as experiences of failure in relationships and academics, all of which suggest to a given youth whether others view him or her as positive, worthwhile, and important.

Three Additional Dimensions Key to Understanding Connectedness in Schools

Many school counselors work with a student body that reflects a great deal of ethnic, racial, and socioeconomic diversity. Increased immigration from countries whose cultural beliefs differ from middle-class American and White Protestant values encourages school counselors to think more broadly about how adolescents experience connectedness as a function of their cultural backgrounds. Three key dimensions that need to be considered are time orientation, collectivism versus individualism, and familism, all of which will influence how the school counselor's efforts to promote assets and connectedness are understood and received by students.

The temporal nature of connectedness: Present and future-oriented connectedness. Distinctions between conventional and unconventional connectedness parallel, but are distinct from, future- versus present-oriented connectedness. Just as connectedness may have both protective and risk-promoting properties, depending on those to whom or to what place the connectedness refers, most places and relationships can be considered to be future or present oriented. Time with friends and family tends to be present oriented as it focuses on the here and now; whereas time spent in school, with teachers, and to some degree even in religious practice, is more oriented to the future. Future-oriented connectedness tends to serve as a protective factor in adolescent development by buffering difficult circumstances and inhibiting impulsive, risky behavior that could pose negative consequences on future opportunities.

Collectivistic versus individualistic connectedness. Some manifestations of connectedness reflect a relational

emphasis, while others reflect a primarily self-oriented, individualistic emphasis (Cooper, 1999). For example, connectedness to schools is largely a reflection of attitudes toward individual achievement. Students feel positive, worthwhile, and important in large part as a function of the assessment process conducted by schools and teachers. By contrast, in families, friendships, neighborhoods, and romantic relationships, interdependent efforts and attention to relationships are deemed more positive, worthwhile, and important.

Familial versus nonfamilial connectedness. Some cultural groups make primary distinctions between family and nonfamily worlds, instead of between youth worlds and adult worlds (as is typical in the United States). For example, in Taiwan, confirmatory factor analyses of the connectedness scales indicate that family/nonfamily is a better way to characterize the nature of adolescent connectedness than is youth/adult-focused (Karcher & Lee, 2002).

The Shape of Adolescent Connectedness

By plotting an individual's or group of students' scale mean scores on a two-dimensional diagram that reflects each of the connectedness dimensions described previously, the shape of a youth's or group's overall connectedness can be represented graphically. The diagram in Figure 39.2 arranges each of the connectedness scales according to these dimensions. In the center of the diagram is *one* (on a one to five metric scale) referring to the lowest possible score. Each scale has a corresponding line that goes outward from the center to a maximum of five. Placing a dot where each group or individual's mean for each scale falls, and then connecting the dots around the center, allows one to see the "shape" of adolescent connectedness.

A triangle can be used to capture this shape by connecting with straight lines just the Family, School, and Friends mean scores for an individual or group. The different shapes of the connectedness triangle convey different emphases. For example, in Figure 39.3, each of three dif-

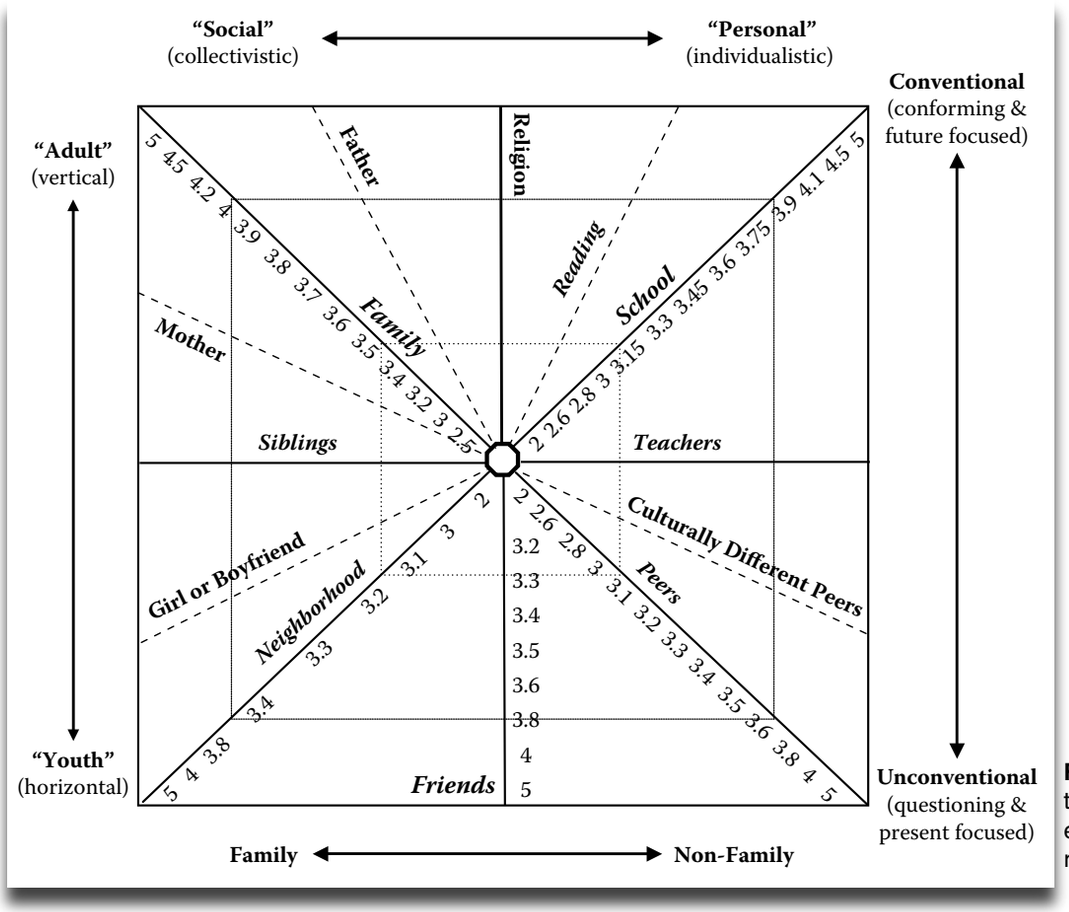


Figure 39.2 A means of plotting the ecology of adolescent connectedness by its dimensions. Copyright© 2007 by Michael J. Karcher.

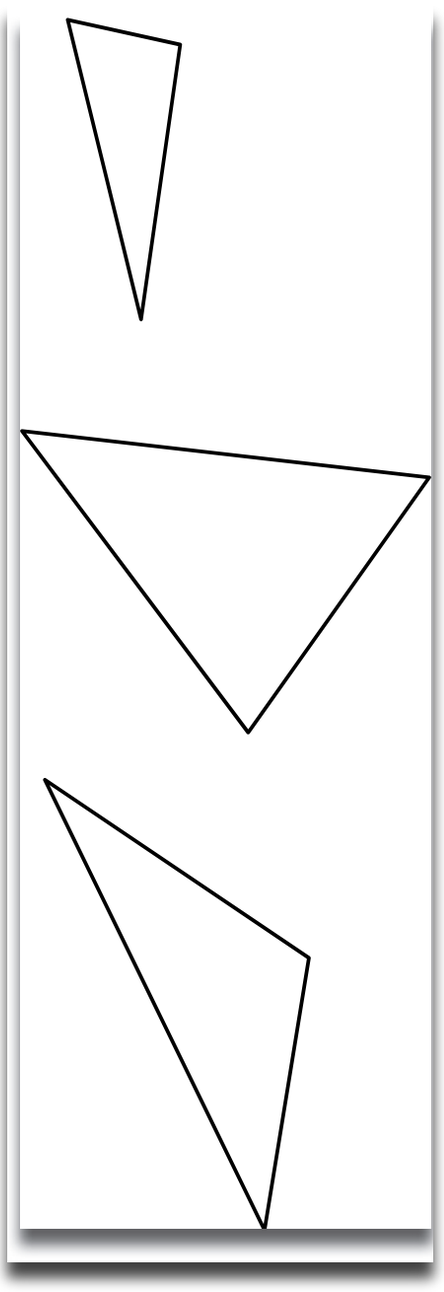

Figure 39.3 The "shape" of adolescent connectedness: Three types. Copyright© 2007 by Michael J. Karcher.

ferent triangles reflects the plotting of the Friends, Family, and School scales for a different pattern of connection.

Shape A in Figure 39.3 reveals that this particular youth prioritizes unconventional connectedness, because the youth rated his or her connectedness to friends as 4.7 out of a 5-point scale, while both conventional worlds of parent and school connectedness were rated below 3 (M = 2.6). Such a youth is likely quite vulnerable to peer pressure and, vis-à-vis, to risk-taking behavior and underachievement (especially when the youth's friends are also highly unconventional in their connectedness). This youth needs help increasing connections with adults and, therefore, may be a good candidate for having a mentor. Receiving extra attention from teachers and being given additional opportunities to interact in adult-oriented contexts also may provide positive experiences that make the youth feel important, valued, and seen as worthwhile by adults.

In contrast, Shape B highlights the importance this youth places on school and family connections (which share conventionality—viz., adult-oriented connections) over unconventional connectedness to friends, neighborhood, and peers. Some counselors might not view this child as having a problem. Certainly, this is not the type of youth typically described by parents, counselors, or teachers for presenting as disconnected, disobedient, or disengaged. However, the virtual absence of any connection with peers does not work to facilitate social skills and peer-based self-esteem. More than likely, this youth demonstrates lower than average social skills or high peer stigmatization that may in fact render the youth at risk for extreme, isolation-related, aggressive outbursts or at least for an unsatisfactory developmental experience with peers.

Shape C conveys a more collectivistic (friend and family) oriented connectedness because individualistic connections (school) were rated lowest. Children whose parents have little experience with postsecondary education, and by extension, many ethnic minority youth, may more often report this pattern of connectedness if their families are not able to model and strongly encourage individualistic achievement at school. Such youth may be more vulnerable to the long-term consequences of de-emphasizing the type of school-based, conventional connections that would help them secure future opportunities for employment or academic achievement. In regards to the particular student in Shape C, there may not be an immediate problem. However, the absence of future-oriented and individualistic connectedness presents warning signs. Such youth should be encouraged to participate in school programs (e.g., sports, extramural, or after-school academic enrichment) in order to help them feel positive, worthwhile, and important at school. These activities can provide opportunities to experience relatedness and belonging to which students can *reciprocate* through increased connection to school.

A Summary of the Theory of Adolescent Connectedness

Drawing on theories of problem behavior, belonging and attachment, and ecological development, we describe adolescent connectedness as an ecologically specific form of engagement with others and the environment. It occurs in response to feelings of belonging and relatedness, which can be fostered by increasing the social support a youth encounters in specific contexts and relationships. Building

on the phenomenon of connectedness as a reciprocation of social support, the school counselor's main leverage gained by using this construct may come through applying the principle of connectedness compensation. In doing so, the counselor may encourage youth high in unconventional connectedness (Shape A) to participate in activities that boost conventional connectedness, but also encourage youth overly high in conventional connectedness and low in unconventional connectedness (Shape B) to engage in social activities with a broader range of peers. The starting place for such work, however, is for the school counselor to understand the behavioral consequences of disconnection in each world and to have tools that can be used to assess students' connectedness. One such tool is the connectedness diagram just described, which provides a way for students to see the shape of their connectedness in terms of the following dimensions: (a) conventional (adult sanctioned) and unconventional (youth sanctioned) connectedness, (b) present-focused and future-oriented connectedness, (c) collectivistic and individualistic connections, and (d) family and nonfamily connections. By considering the interplay of these connectedness dimensions, and creating opportunities for youth to better understand the "shape" of their own ecology of connectedness, school counselors may be better able to target meaningful interventions for youth and measure important postintervention changes in the adolescents' connectedness. Being successful at both, however, assumes the school counselor has a grasp of the research on connectedness and a valid assessment tool handy.

Research

Establishing and maintaining connectedness to others, to society, and to oneself is a pervasive human concern (Baumeister & Leary, 1995; Gilligan, 1982; Hagerty et al., 1993; Kohut, 1977; Nakkula & Selman, 1991). Baumeister and Leary proposed, 25 years after Maslow (1968) described belongingness as the third most fundamental need of the self, that belongingness is perhaps the most important psychological resource for overall human well-being.

Adolescents Need a Balance of Connectedness Across Their Social Ecology

Connectedness is a function of the need to belong, such that when an individual in one social ecology does not experience belonging and relatedness, he or she will become more connected to other social ecologies as a compensatory act (Baumeister & Leary, 1995). For example, research confirms that when disconnection occurs with family members, connectedness with friends may increase; when adolescents become disconnected from school, they often seek connectedness outside of school in their neighborhood (see Hirschi, 1969; Joo & Han, 2000). Other research suggests that adolescents' sense of self is born out of these sometimes divergent connections to family, teachers, friends, and peers (Buhrmester, 1990; DuBois et al., 1996) which facilitate the development of a sense of oneself in the present as well as oneself in the future.

An Emphasis on Unconventional Over Conventional Connectedness Promotes Risk Taking

Because connectedness reflects the presence (often in the form of expectations) of such profoundly important experiences as relatedness and belonging, connectedness has been linked to physical health, clinical disorders, and risk-taking behaviors (Bonny, Britto, Klostermann, Hornung, & Slap, 2000; Hendry & Reid, 2000; Lee & Robbins, 1998; Resnick et al., 1993). A long line of research on delinquency and violent behavior among youth shows that connectedness and alienation are intimately linked with problem behaviors (Hawkins, Catalano, & Miller, 1992; Hirschi, 1969; Jessor & Jessor, 1977) and, therefore provide important targets for effective prevention programs in schools (Allen, Kuperminc, Philliber, & Herre, 1994; Hawkins, Von Cleve, & Catalano, 1991; Jason & Kobayashi, 1995; Jessor, 1992).

Not all forms of connectedness decrease risky behavior, however, because the protective functions of connectedness vary across the relationships and contexts of adolescents' lives. Depending on the individual youth and his or her specific set of peers, connectedness to peers can reflect the conventions of either the adult world or the unsupervised activities and norms of the adolescent world. As one good example, it is commonly believed that peer relationships facilitate misbehavior through processes of negative peer pressure, yet research shows that associating with conventional peers is one of the best protective factors against violent behavior (Hawkins, Farrington, & Catalano, 1998; Hawkins et al., 1991; Olin, 2001).

Connectedness to friends, however, is usually positively correlated with risk taking (Karcher, 2002; Karcher & Finn, 2005). Although connectedness to friends could be called conventional because most parents/adult caretakers want their children to have friends, connectedness to friends serves a different function than connectedness to school or family does.

> Adolescents who describe positive relationships with parents and teachers show greater adaptation to school in terms of their academic coping, engagement, self-regulation, and perceived control. Relationships with friends are generally unrelated

> to these outcomes, suggesting the different functional significance of students' relationships during early adolescence. In addition, adolescents who strongly identify with parents and teachers show more positive school adjustment and motivation, whereas emulation of friends is negatively related to these variables. (Lynch & Cicchetti, 1997, pp. 83–84)

Therefore connectedness to friends has *both* positive and negative effects on adolescent development and behavior. On one hand, any connectedness to friends is better than no connectedness at all in terms of promoting social development, avoiding experiences of alienation, and preventing aggression (Collins, 2002; Nakkula & Selman, 1991). On the other hand, when connectedness to friends is high, but connectedness to school or family low, this imbalance increases youths' risk for engaging in risk taking and misbehavior (Jessor, 1993).

More recently, Dishion, R. Jessor, and others (i.e., Dishion, McCord, & Poulin, 1999; Jessor, 1992; Patterson, Dishion, & Yoerger, 2000) have found that spending unsupervised time in one's neighborhood, with friends, or in other youth-governed contexts increases the risk that a youth will engage in unconventional behaviors. Taken to the extreme, unconventional connectedness can lead to activities that are unlawful and potentially damaging to self and others (Jessor & Jessor, 1977). Behaviors, such as stealing, drinking, delinquency, and violence, are most common when strong connectedness to friends is not balanced by equally strong connectedness to school or to family (Hirschi, 1969; Olin, 2001). In this way, conventional connectedness serves as a control against nonnormative, antisocial, illicit, and aggressive behaviors (Hirschi).

School Counselors Should Avoid Grouping Highly Unconventional Youth

The conventionality phenomenon presents an important consideration for school counselors when choosing members for group counseling. Although formally screening youth in order to identify appropriate candidates for school counseling groups or other interventions has not been a standard practice in school counseling (Ripley & Goodnough, 2001; Sullivan & Wright, 2002), there is persuasive research suggesting that it should be. For example, Dishion et al. (1999) presented surprising findings from a 30-year study of comprehensive services provided to youth at risk for delinquency. Analyses revealed that the long-term impact of aggregating at-risk youth within groups (e.g., in a counseling group) was to *increase* delinquency, regardless of the efforts of the counselors. Given this, it is wise to selectively include within group counseling both those youth at risk for specific problems and those not at risk. In terms of the connectedness framework, this means school counselors should include youth with high and youth with low levels of unconventional connectedness as opposed to targeting and aggregating only unconventionally connected youth within the group counseling setting.

The Promise and Perils of Connectedness Compensation

There appears to be an interaction between forms of conventional and unconventional connectedness, such that when connectedness is not achieved in one context it is overemphasized in others (Ainsworth, 1989). Baumeister and Leary (1995) argued that because the need to belong is so pervasive, there is a compensatory function which allows the absence of belonging in one ecology (e.g., family) to be countered by belonging in another (e.g., friends). They stated,

> Relationships should substitute for each other, to some extent, as would be indicated by effective replacement of lost relationships partners and by a capacity for social relatedness in one sphere to overcome potential ill effects of social deprivation in another. (p. 500)

Although the absence of conventional connectedness with one parent can be compensated by connectedness with the other, unconventional connectedness cannot take the place of absent parental connectedness (van Aken & Asendorpf, 1997). The intervention opportunity presented by this compensatory function is the possibility for conventional experiences and relationships, such as in after-school programs or through natural mentoring by teachers (DuBois & Silverthorn, 2005), to compensate for prior deprivations of conventional connectedness that resulted from poor parental bonding, peer rejection, or school failure and underachievement.

The Ecology of Connectedness Widens and Becomes More Unconventional During Adolescence

R. Jessor and S. L. Jessor (1977) found that, as the adolescent's ecology widens, so too do the opportunities to engage both in unconventional behaviors that are encouraged by peers (e.g., risk-taking behaviors) and in contexts not governed by parents (e.g., the neighborhood). This is partly because of normative declines in conventional behaviors (e.g., reading, working at school, and spending

Table 39.1 Connectedness Report: District Profile of Average Level of Connectedness by Sex, Grade, & Related Developmental Asset.

Connectedness Domain	**Related Developmental Asset**	**Conn. for kids with/out asset**		**Average Level by Sex**		**Mean Level of Connectedness in Each Grade**

time with family) relative to the increased opportunities to spend time with friends.

In several studies, both with adolescent samples from the United States and Asia, it appears that conventional connectedness declines during adolescence while unconventional connectedness increases (Karcher, 2001; Karcher & Lee, 2002). These differences in mean levels of connectedness across the adolescent social ecology over time are illustrated in Table 39.1. This table is based on data from 342 students from a Midwestern town who completed both the Hemingway measure and the SEARCH Developmental Assets survey. Students in grades 6 through 12 were equally represented. The majority were Caucasian (n = 265) and 185 were female. For the present purpose, notice mean changes among students in connectedness to school between 6th, 9th, and 12th grades, which go from 3.8 to 3.5 to 3.3 during that time period (with 5 being very connected and 1 being very disconnected). Similarly, changes in connectedness to parents are 3.9 to 3.7 to 3.6 during this time. This is expectable as increased freedom and mobility invite increased time spent with friends, peers, and romantic partners during adolescence. It also suggests that an *imbalance* between conventional and unconventional connectedness is *normal* in adolescence.

Girls Usually Report Higher Levels of Connectedness Than Boys Do

Gender differences have received perhaps the most attention within the research on connectedness even though many of the studies of connectedness actually measured belonging. Statistical tests of the hypothesis that girls report greater relatedness and belonging than boys has been the focus of much research (e.g., Lang-Takac & Osterweil, 1992), but empirical studies "connectedness" that used measures of belonging and relatedness (rather than connectedness) have failed to consistently reveal clear gender differences (Hagerty et al., 1993; Harter, Waters, Pettit, Kofkin, & Jordan, 1997; Jacobson & Rowe, 1999; Lee, Keough, & Seagal, 1999; Lee & Robbins, 1995). In most studies using the connectedness measure described in the following section, girls scored higher on all of the scales of connectedness except on the Connectedness to Neighborhood and Self-in-the-Present scales (Karcher, 2001, 2001a; Karcher & Finn, 2005; Karcher & Lee, 2002;). Consistent with these findings, Table 39.1 reveals the girls, in this Midwestern sample of 342 middle and high school students, reported greater connectedness than boys did. This may be interpreted to mean that while experiences of belonging and relatedness may not differ between adolescent boys and

girls, the response to these feelings—that is, their efforts to connect with others—appears to be stronger for girls than boys. These differences, however, may be detected only with a measure of adolescents' *engagement* (i.e., of connectedness) rather than of belongingness or relatedness.

A Description of *The Hemingway: Measure of Adolescent Connectedness*

The Hemingway: Measure of Adolescent Connectedness is a self-report instrument that includes scales that assess engagement through caring for and involvement in close relationships and important contexts. The Hemingway consists of 78 items that are averaged to create scales for 15 ecological worlds and 4 composite scales. The 15 scales fall into 3 dimensions of connectedness: self, others, and society. *Connectedness to self* includes 2 scales: (1) positive feelings about the self in the present (e.g., self-esteem; DuBois et al., 1996; Harter, 1999) and (2) sense of one's self in the future (Nakkula & Selman, 1991). *Connectedness to others* includes 5 scales: connectedness to (3) parents, (4) friends, (5) teachers, (6) siblings, and (7) peers. Because the scales measuring connectedness to religion, race, and romance are sometimes problematic for school administrators, both short and long versions were created. Connectedness to others scales which are included only in the longer version are connectedness to one's (8) mother, (9) father, (10) a romantic partner, and (11) culturally different peers. *Connectedness to society* includes scales measuring connectedness to (12) school, (13) neighborhood, and (14) reading. Included in only the longer version is the (15) connectedness to religion scale. The 4 composite scales reflect the mean of all scale items in each of 4 domains: family (parents and sibling items), friends (friends and neighborhood items), school (school and teacher items), and self (present and future self items).

The psychometric properties of the scales across several samples as well as findings from multiple validity studies can be found in the manual and validity study (Karcher, 2001, 2003), which is available upon request from Karcher (first author). In addition, in the last column in Table 39.1, reliability estimates for the sample used for the analyses discussed previously are reported.

Scoring. Responses to each of the items are made using a 5-point, Likert-type response scale which includes (1) not true at all, (2) not really true, (3) sort of true, (4) true, and (5) very true. There is at least one reverse-scored item in each scale (identified in bold in Table 39.2). The items within each of the 15 scales are averaged (once the reverse worded items are reverse-scored) to get separate scale score means.

Table 39.2 Items for Several Scales of the Hemingway Measure of Adolescent Connectedness

Scale Items—Reverse score items 2, 7, 13, 18, 26, 30, 34, 45, 51, 55, 64, 70, 71

Neighborhood (6 items)

(1) I like hanging out around where I live (like my neighborhood).
(11) I spend a lot of time with kids around where I live.
(21) I get along with the kids in my neighborhood.
(31) I often spend time playing or doing things in my neighborhood.
(41) I hang out a lot with kids in my neighborhood.
(51) **My neighborhood is boring.**

Friends (6 items)

(2) **Spending time with friends is not so important to me.**
(12) I have friends I'm really close to and trust completely.
(22) Spending time with my friends is a big part of my life.
(32) My friends and I talk openly with each other about personal things.
(42) I spend as much time as I can with my friends.
(52) My friends and I spend a lot of time talking about things.

Self-in-the-present (6 items)

(3) I can name 5 things that others like about me.
(13) **There is not much that is unique or special about me.**
(23) I can name 3 things that other kids like about me.
(33) I really like who I am.
(43) I have special hobbies, skills, or talents.
(53) I have unique interests or skills that make me interesting.

Parents (6 items)

(4) My family has fun together.
(14) It is important that my parents trust me.
(24) I enjoy spending time with my parents.
(34) **My parents and I disagree about many things.**
(44) My parents and I get along well.
(54) I care about my parents very much.

Siblings (5 items)

(5) I have a lot of fun with my brother(s) or sister(s).
(15) I feel close to my brother(s) or sister(s).
(25) I enjoy spending time with my brothers/sisters.
(35) I try to spend time with my brothers/sisters when I can.
(45) **I try to avoid being around my brother/sister(s).**

School (6 items)

(6) I work hard at school.
(16) I enjoy being at school.
(26) **I get bored in school a lot.**
(36) I do well in school.
(46) I feel good about myself when I am at school.
(56) Doing well in school is important to me.

(*Continued*)

Table 39.2 Continued

Peers (6 items)
(7) **My classmates often bother me.**
(17) I like pretty much all of the other kids in my grade.
(27) I like working with my classmates.
(37) I get along well with the other students in my classes.
(47) I am liked by my classmates.
(57) I rarely fight or argue with the other kids at school.
Teachers (6 items)
(8) I care what my teachers think of me.
(18) **I do not get along with some of my teachers.**
(28) I want to be respected by my teachers.
(38) I try to get along with my teachers.
(48) I always try hard to earn my teachers' trust.
(50) I usually like my teachers.
Self-in-the-Future (5 items)
(9) I will have a good future.
(19) Doing well in school will help me in the future.
(29) I do things outside of school to prepare for my future.
(39) I do lots of things to prepare for my future.
(49) I think about my future often.
Reading (4 items)
(10) I enjoy spending time by myself reading.
(20) I like to read.
(30) **I never read books in my free time.**
(40) I often read when I have free time.
Kids from other cultures (3 items)
(60) I like getting to know kids from other cultural or racial groups.
(65) I would like to know more people from different cultural groups.
(69) I like getting to know people who are culturally different from me.

The Hemingway is one of few self-report measures of adolescent connectedness that has undergone considerable empirical scrutiny and generated considerable validity evidence (Karcher, 2001). The measure was developed through a series of exploratory and confirmatory factor analyses, which revealed the same family, friend, and school higher order factors (underlying scale groupings) across several U.S. samples. These three factors, which were used to create Figure 39.2, may be described as the Social Connectedness (i.e., to friends), Academic Connectedness, and Family Connectedness composite scales. These composite scales reflect the three corners of the Y-framed triangle in the Connectedness Diagram (Figure 39.2). The *unconventional connectedness* factor includes connectedness to friends, the neighborhood, a self-in-the-present, and romantic partner scales. The *academic connectedness* factor includes connectedness to school, teachers, peers, culturally different peers, reading, and self-in-the-future scales. The *family connectedness* factor includes the connectedness to parents, siblings, mother, father, and religion scales.

The scales in each of these three factors also can be characterized in terms of the dimensions or continuum described earlier: *temporality, conventionality,* and *relational orientation* (collectivist/individualist; family/nonfamily). The items in each of the scales reflect the two primary means of connection—through activity or involvement and through caring (e.g., "I work hard at school" and "I enjoy being at school"). These scales also reflect a time orientation. The family and social composite connectedness scales are generally present oriented, and the academic connectedness scale is typically future oriented. Scales measure either conventional, adult-mediated behaviors and attitudes that are vertical (adult-driven) and future-oriented or unconventional behaviors and attitudes that are horizontal (peer-driven) and questioning and which reflect youth-directed behaviors and youth-specific attitudes in the present. Finally, the collectivistic and family-oriented scales emphasize larger groups and social hierarchy, and conversely, the individualistic, nonfamily, and future-oriented scales reflect individual (self-directed) connections and achievement. These continua are presented as two-way arrows in Figure 39.2.

The Value of Connectedness in Predicting Assets

We believe the Hemingway connectedness measure can facilitate the use of the Developmental Assets framework and survey by providing an interim or proxy measure of assets. Here we provide just three examples of this. First, in Figure 39.2, the two concentric squares (dotted and thin lines) reflect the mean scale scores for two groups of youth from a Midwestern sample of 224 middle and high school aged youth. A sample of youth who completed both the SEARCH Institutes *A/B Assets Survey* and *The Hemingway: Measure of Adolescent Connectedness* sample was divided into three groups: low, medium, and high internal assets. The inside line reflects the mean for youth reporting low (fewest) internal assets, and the second line reflects the mean scale score for those youth reporting many high (the most) developmental assets. These lines provide one gauge of whether a given youth or group's scale score should be considered low or high (keeping in mind that girls tend to report .15 to .30 higher mean scores than boys on most scales; see Table 39.1).

Second, we can compare scores on specific connectedness scales with the presence/absence of related developmental assets. One important asset is the "Adult Role Models" asset. Using data from the same Midwestern sam-

ple described earlier, we could reliably predict (with 83% accuracy using logistic regression) the presence or absence of this asset from the youth's mean scale score on the connectedness to teachers scale (see second row in Table 39.1). Table 39.1 illustrates the prediction accuracy of several key Developmental Assets from related connectedness scales. The first two columns of numbers indicate the mean on each connectedness scale for youth who *did* or who *did not* have the related asset. In parentheses is the degree of predictive accuracy. For example, connectedness to reading scores predicted the presence or absence of the asset "Reading for Pleasure" with 88% accuracy. The connectedness to religion scale (not shown) predicted having the Religious Community asset with 84% accuracy. In short, several of the connectedness scales can serve as reliable proxy measures of specific assets.

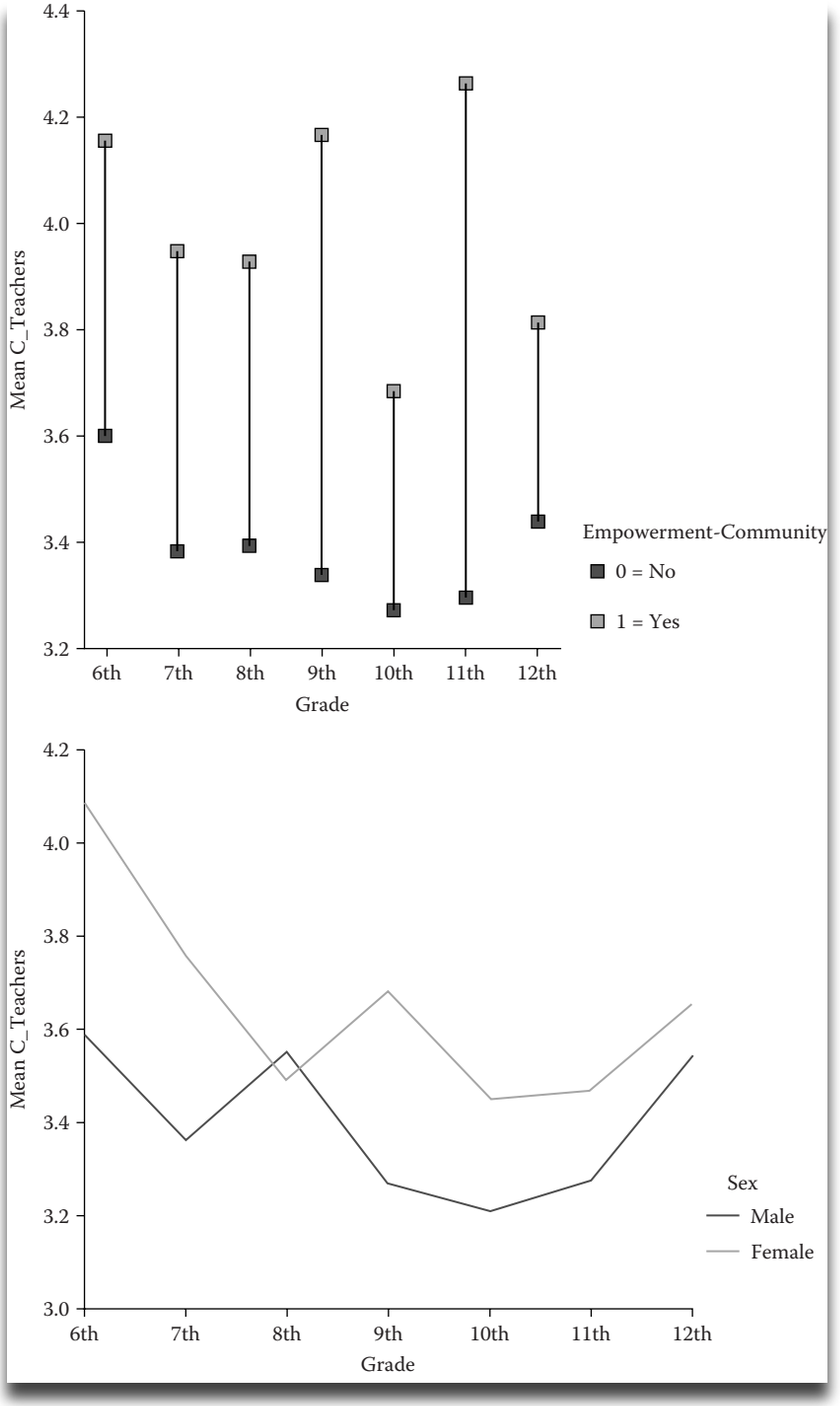

Figure 39.4 Two charts of connectedness to teachers across adolescence by assets and sex. Copyright© 2007 by Michael J. Karcher.

For a given school district, the relationship between Developmental Assets and connectedness may be linked in order to identify targets for interventions or guidance program goals. For example, in Figure 39.4, the means for connectedness to teachers at each grade were plotted for those who did and did not report having the asset "Community Values Youth," which assesses whether students perceive that adults in their community value youth. Across all grades, youth whose means on the connectedness to teachers scale was low (e.g., between 3.4 and 3.5) did not feel their community valued youth. How much improvement in connectedness to teachers would indicate that students in general did feel youth were valued by adults in the community? Well, this depends on the grade, because the mean level of connectedness to teachers among youth who had the "Community Values Youth" asset ranged from 3.7 in 10th grade to 4.3 in 11th grade. However, a good range to set as a goal to measure the success of an intervention to increase this asset among students might be to have the majority of youth score between 3.8 and 4.2, depending on the grade. A school district could begin a campaign to promote feeling valued by starting with teacher relationships in the school but extending efforts beyond the school as well, and measure changes in connectedness to teachers every semester until that goal is achieved.

Charting Developmental Trends for Boys and Girls Across Grades to Identify Program Goals

Another way to use research to link the Developmental Assets and connectedness scales in a manner that can help school counselors plan guidance activities and program objectives is to plot connectedness scales for boys and girls across grades. In the second chart in Figure 39.4, we see that girls report greater connectedness to teachers, but similar to boys, the girls show declines in connectedness to teachers from middle school to high school. By 11th grade, both boys and girls (those who have not dropped out, of course) are beginning to report more connectedness to teachers. The gap between the sexes is largest in 6th and 9th grades in this school district, which is a time of transition from one school level to another. Boys, it appears, are in particular need of connectedness to teachers at these times. For both sexes, the key times to target teacher connectedness (e.g., as a way to increase the "Community Values Youth" asset) appear to be during the 7th, 8th, and 9th grades. Such efforts could ward off declines in the assets as well.

Practice

A comprehensive school guidance and counseling program provides an organizational framework with a specific configuration of planned, sequenced, and coordinated guidance and counseling activities and services based on student, school, and community needs and resources (Gysbers & Henderson, 2006). As previously stated, many school counselors are stretched for time and must serve the needs of parents, teachers, administrators, and students. However, through involving teachers, parents, and administrators as well as the students in a comprehensive guidance and counseling program, greater clarity about the guidance program goals and the role of the counselor can be achieved. Our experience suggests that school counselors are less likely to be pulled in 100 different directions when they (a) base goals and related services on assessed needs of students and other stakeholders, (b) make the content and focus of their guidance program known to teachers, parents, and administration, (c) make clear to students and stakeholders how the four key components of their guidance programs (system support, guidance curriculum, individual student planning, and responsive services) are linked, and (d) demonstrate the effectiveness of these programmatic efforts.

The Developmental Assets framework (presented by the SEARCH Institute) is one approach chosen by many school districts with which to organize their comprehensive guidance model. The Northside Independent School District in San Antonio is an example of a large school district (the sixth largest in Texas) that has oriented its programming around the Developmental Assets framework. This district was the testing ground for Gysbers and Henderson's (2006) developmental guidance model (which informed and mirrored the ASCA, 2003, model). We also know this district well. It is where two of the authors worked, one as a licensed professional counselor and the other as the director of guidance, and from this district, the third author received his high school diploma. Northside, already a nationally recognized program, enhanced its model by using the Developmental Assets framework and by developing materials and guidance activities based on this approach. The Developmental Assets framework has been used district-wide to facilitate guidance program staff development efforts with counselors, teachers, administrators, and staff. The model informs such activities as campus mentoring, parent programs, policies, the content of the guidance program curriculum, intervention services, and the district's federal Safe and Drug Free Schools programming.

The Assets framework has provided a useful model for many of Northside's programs but has not provided an accessible tool for assessing the needs that individual students bring to the classroom. Formal and informal asset surveys have been used to assess the presence of assets among the student body at Northside at the district level. The results have provided a collective profile of students but no data representing the individual student's assets.

This is because the Developmental Assets survey cannot be conducted frequently enough to gauge change resulting from guidance, individual planning, and responsive services for subgroups of students over a short period, and it is not currently used for individuals, only for groups (e.g., districts).

For these reasons, *The Hemingway*: *Measure of Adolescent Connectedness* (Karcher, 2001) can be utilized as a complementary tool in order to also assess individual student needs regarding their connectedness to friends, school, and family, and by extension provide a proxy measure of Developmental Assets for individual students. This allows counselors and others to better plan and provide needed services for individual students. Combining the specificity of information provided by the connectedness measure with the collaborative and positive effects on school climate that a program oriented around the 40 Developmental Assets framework can engender, school counselors can be better poised to enhance student success across the four delivery components of a comprehensive guidance program with this integrated approach. In the sections that follow, we provide examples of how the connectedness measure and its accompanying constructs can be used to facilitate an asset-promoting comprehensive program of school guidance in a school district.

System Support: Teaching Teachers About Connectedness and Developmental Assets

The work that school counselors do with teachers can indirectly help students form connections to the school and foster developmental assets. By providing in-service training to staff, in accordance with the systems support component of the comprehensive guidance program model (ASCA, 2003), counselors can provide leadership and advocacy in promoting systemic change on behalf of students. Providing in-service training using the Developmental Assets framework to teachers and other staff members is a useful way of helping them promote students' healthy development and protect youth from negative and harmful behaviors (Benson et al., 1995). The 40 Assets also reveal types of youth-oriented attitudes and activities that promote or discourage students' conventional connectedness to the school.

As one example of promoting students' connectedness to school, counselors can work with teachers through staff development sessions to teach them how to utilize the connectedness constructs and assessment. Some teachers might want to use the connectedness measure to identify needs among their students. Either during staff development or with smaller groups of interested teachers, school counselors can illustrate for teachers the uses and interpretation of the measure. These teachers can be taught how to use the data to address and promote those assets that are absent in the students' lives. For example, if a student's connectedness profile suggests a marked degree of unconventional connections to peers, teachers and others can collaborate to build more conventional connections to peers through individual peer mentoring or collaborative learning projects. Teachers might also encourage youth who are disconnected from school to participate in school organizations related to the students' expressed interests.

Through such system support activities, school counselors also can indirectly help facilitate experiences of belonging and relatedness in classrooms, hallways, and other areas of the school that may result in increased student connectedness. Through small and large group staff development presentations on the Developmental Assets and the connectedness research mentioned previously, school counselors may promote a fuller utilization of comprehensive guidance activities by teachers and students.

School Guidance Curriculum: "The Connections I Make"

Classroom guidance provides counselors an opportunity to become familiar with the student climate as well as to screen students for appropriateness for other services (e.g., individual and group counseling, mentoring, tutoring, or after-school programs). School counselors may find the connectedness scales particularly useful in guidance lessons because they provide a framework for introducing students to the four domains of adolescent connectedness (viz., friends, school, family, and self).

Cobia and Henderson (2003) advised that all well-designed guidance lessons have a clear purpose, age-appropriate activities, coordinated and sequential lessons, and a summary or evaluative wrap-up. Each guidance lesson is designed to reach all students by delivering concepts that build on those learned in previous guidance lessons. Even though introducing the four domains of adolescent connectedness to students through classroom guidance must be delivered in an age-appropriate manner, it also can be done in ways that are fun, interactive, and memorable.

One example of a guidance lesson that can create an interactive and playful way to introduce the connectedness domains is entitled "The Connections I Make." This lesson asks students to place themselves on one or the other end of connectedness continua depicted in Figure 39.2. The goal of this guidance lesson is for students to better understand how much importance they place in different forms of connectedness by weighing the pros and cons of conventional and unconventional connectedness. This is achieved through two different activities. The first activity is interactive and interpersonal, and the second is reflective and more personal. Before beginning the activity, stu-

dents are asked to complete the connectedness measure. Students should be told their answers will be kept confidential but that the counselor might talk with students afterwards about their own responses. To foster buy-in, the students should clearly understand that this measure provides the basis for the content conveyed in that day's and perhaps in subsequent guidance lessons.

After the students complete the connectedness measure, it is set aside, unscored, and students are asked to participate in the first activity. This activity requires them to identify their connectedness statuses by indicating which of two ends of each connectedness continuum shown in Figure 39.2 they more commonly engage in. To indicate their preference, students are asked to move from one side of the room to the other, providing a visual representation of each end of the continuum. The goal is for each student to identify the types of connections he or she is most inclined toward for each of the dimensions listed in Figure 39.2.

In the second part of the lesson, the school counselor guides the students through a student-centered discussion by encouraging the class to discuss the pros and cons of each type of connectedness. These dimensions should be discussed in an age-appropriate manner, such that discussing the terms conventional and unconventional connectedness may only be appropriate with older youth. Instead, the basic terms—youth versus adult focused—can be defined and written on either an overhead screen or chalkboard. Once defined, the counselor sets the stage for discussion by providing some of the research findings presented in the research section of this chapter. For example, if the youth are familiar with the Developmental Assets framework, this language can be incorporated into the discussion by linking assets to types of connectedness. The pros and cons of high connectedness in each world should be presented by the counselor for middle school students, while for high school students, these can be solicited from the students themselves. During the summary portion of the guidance lesson, the counselor asks students for feedback regarding lessons they learned in order to make sure their understanding is accurate and so that no one feels criticized or labeled. The goals of this activity are to help students identify variations in their connectedness and to more fully understand the benefits and risks posed by each kind of connection as well as to help school counselors identify the needed direction of future guidance lessons or individual planning sessions. Similarly, the counselor's next step toward integrating connectedness-promoting activities into the guidance program can be to take the students' connectedness measures, score them, and use the data to identify individuals who could be appropriate for individual planning meetings or specific responsive services.

Individual Planning: Assisting Present-Oriented Students

Having completed this guidance activity, the school counselor now has accessed valuable data through the collection and scoring of the completed connectedness measures and through information gathered from the guidance activity discussions. The individual student-planning component of the comprehensive guidance program provides the counselor with a vehicle for assisting all students in developing, monitoring, and assessing educational, occupational, and personal goals (ASCA, 2003). However, the connectedness data gleaned from the classroom guidance activity can be used to identify and assist students whose connectedness profile suggests a high degree of unconventional connectedness or a greater orientation to the present than to the future. Using this information, the school counselor might invite such students to participate in individual planning meetings. In doing so, the school counselor could then work with targeted students individually or in groups in order to establish future-oriented goals related to specific careers. A sample activity may include an individual planning session where the student and counselor investigate the student's areas of interest and strengths with the assistance of a computer-based interest inventory. This can help the student begin to connect present performance in the classroom and potential participation in related clubs and community activities to future interests and aspirations.

Responsive Services: Incorporating Unconventionally Oriented Youth More Fully Into School

Finally, working in the component of responsive services, school counselors can use the measure of adolescent connectedness as a tool for screening students for appropriate counseling groups. Keeping in mind that there are two main types of connectedness—conventional and unconventional—the counselor's goal in group selection should be to identify youth whose interpersonal needs, problems, and skills could complement those of other students in the group. Doing so can help to avoid the problem described by Dishion et al. (1999), wherein well meaning interventions actually become contexts for deviancy training.

Once the students have been identified for a group, connectedness may be used to provide the underlying theme for the group's work or to help link the youths' connectedness to specific developmental assets. For example, the school counselor might encourage discussions centered on the importance of establishing a balance between conventional and unconventional connectedness. The connectedness terms also may provide a shared language for the group, allowing a variety of individual problems (e.g.,

dealing with divorce, problems with peers, risk-taking behaviors) to be discussed indirectly and more inclusively by referring to the role of connectedness within each of these individual issues.

Another way to introduce the issue of connectedness would be for the school counselor to start the group by asking group members to determine with which one of the three shapes in Figure 39.3 they most identify. The school counselor can then facilitate a discussion regarding the group members' experiences of connection and disconnection and regarding how these experiences have led the students to take on the "shape" they identified. One goal the counselor may pursue is helping the group members encourage one another to seek out connectedness where it may previously have been lacking in the youth's life. The counselor might encourage group members both to create an action-oriented connectedness plan that facilitates their own connectedness and to support fellow group members' creation and the achievement of their own plans.

Counselors also should move beyond promoting feelings of belongingness and relatedness in the counseling group to helping students find ways to establish desired connections outside the group. For example, a group member may lack connectedness to school and decide he or she would like to become more involved at school. This group member's action-oriented connectedness plan may include joining a school club, sport, or after-school program. The school counselor could assist this student by helping the student identify *and achieve* concrete steps toward becoming more connected to school. For example, the counselor may assist the student by setting up the initial appointment for the student to meet with the club sponsor or coach.

Afterword: The Naming of "The Hemingway"

In 1994, Brad Powell and Father Patrick Gahan, at Saint Stephen's Episcopal School in Austin, Texas, asked the measure's creator, Michael Karcher, to develop an instrument that could help them assess student changes resulting from their cross-age peer mentoring program. The main concept of connectedness was derived from a paper by Michael Nakkula and Robert Selman (1991), both of whom were Karcher's academic mentors at Harvard. Nakkula's notion of youth development suggests that programs should serve to promote youth's "interpretation of his or her connectedness to the world over time" (p. 186). This suggestion served as the basis of *The Hemingway* and guided the development of adolescent connectedness theory (Karcher, 2001).

The name, Hemingway, also has its origin in the biography of Michael Nakkula. The first son of a blue-collar family in the Upper Peninsula of Michigan, Michael Nakkula was the first individual in his family to attend college. Nakkula's subsequent attainment of a professorship at Harvard led Karcher to ask him how he understood his extraordinary academic achievements. Nakkula explained his connectedness to academe through a story involving one of his high school teachers, who, after reading a paper Nakkula wrote for a class assignment, told Nakkula that he wrote like Hemingway. The interpretation Nakkula made about his connectedness to school and the future (that he had special writing gifts) helped him achieve his potential in the world of postsecondary education and ultimately as a published author. In honor of that high school teacher's impact, this measure of adolescent connectedness was named *The Hemingway*.

Acknowledgments

We would like to thank Gwen Louden-Gerber for her feedback on an early draft of this chapter. This chapter incorporates and further elaborates text, figures, and concepts from an earlier work on connectedness in schools by M. J. Karcher (2004) entitled, *Connectedness and School Violence: A Framework for Developmental Interventions*, which was printed in E. Gerler (Ed.), *Handbook of School Violence* (pp. 7–42), Binghamton, NY: Haworth Press. Permission to reproduce text and Figure 39.1 has been provided by the Haworth Press and Ed Gerler. Copies of the measure (both short and long forms in English and Spanish), scale norms, and related research can be found at www.adolescentconnectedness.com.

COURTNEY K. MILLER
Catholic Social Services, Lincoln, Nebraska

Introduction

Bullying and peer victimization are ubiquitous phenomena that many students experience during their school years. While all students have the right to learn in a safe and nonthreatening environment, bullying usurps students of this basic right. This chapter will link theories and research about bullying behaviors, which will form the foundation for a review of effective school-based practice. Intervention programs that have been empirically evaluated will be presented, keeping in mind the developmental needs of students as they progress from preschool through high school.

Definitions

At the outset, we would like to provide working definitions for the constructs described in this chapter. We will define *bullying* according to the classic definition put forth by Dan Olweus: *Bullying* involves either physical or verbal negative actions inflicted by one or more persons upon another person. These actions are intentionally meant to cause harm and are repeated over time in a relationship characterized by an imbalance of strength and/or power (Olweus, 1993a). *Victimization* is defined in the following, "A student is being victimized when he or she is exposed, repeatedly and over time, to negative actions on the part of one of more other students" (Olweus, 1993a). Additionally, we have adopted the Institute of Medicine's (IOM) clinically accepted framework of "prevention," "treatment," and "maintenance" as a rubric for classifying empirically evaluated bullying prevention and intervention programs (IOM, 1994). The Institute of Medicine's framework is population-based, makes specific distinctions between prevention and treatment, and addresses multiple facets of risk and protective factors and their mutual effects. This framework is a useful rubric, as it emphasizes not only the importance of prevention and treatment, but also the importance of maintaining positive treatment gains over time.

Role of the School Counselor in Bullying Prevention and Intervention

The role of the school counselor in bullying prevention and intervention is vital. Often, school counselors are the first professionals in the schools to hear about bullying incidents. Additionally, school counselors are often trained in conflict resolution, individual counseling, and group counseling. These valuable skills lay the foundation for the school counselor to be the logical point person for bullying prevention and intervention efforts. As such, school counselors are key players in preventing, treating, and maintaining effective bullying programming.

Role of Type of School and Bullying

Researchers have examined whether school setting (i.e., geographic location) is related to bullying behaviors among youth. In the first, large-scale investigation (N = 15,686) of bullying among U.S. youth, there were no significant differences in frequency of being bullied among youth from urban, suburban, town, and rural areas (Nansel et al., 2001). This investigation, however, noted slight

differences with regard to bullying others across geographic location. Approximately 2% to 3% fewer suburban youth endorsed participation in moderate bullying and 3% to 5% more youth in rural settings reported ever bullying.

Although the majority of research to date has been in urban and suburban school settings, several studies have specifically examined bullying in rural settings. The prevalence of bullying in seven rural elementary schools was examined by surveying students, parents, and teachers (Stockdale, Hangaduambo, Duys, Larson, & Sarvela, 2002). Surveys were completed by 739 fourth-, fifth-, and sixth-grade students, 367 parents, and 37 teachers. In this study, students reported higher prevalence of bullying than did parents or teachers, and their reports were associated with aggression, attitudes toward violence, and perceptions of school safety. Based on these results, these researchers concluded that bullying behavior is prevalent in rural elementary schools.

A more recent study conducted by Dulmus, Theriot, Sowers, and Blackburn (2004) examined the prevalence of bullying at three rural schools, sampling students in grades 3 through 8 with the Olweus Bully/Victim Questionnaire. Results indicated that of the 192 students included in this study, 158 children (82.3%) reported having experienced some form of bullying at least once in the past three months. While these results may suggest that school bullying is a larger problem in rural communities than in urban areas, additional research is warranted due to variations in the definition of bullying and methodological problems across studies.

The Explanatory Power of Theory

One weakness in the bullying literature is that much of the empirical work in this area is largely atheoretical; however, there are several cognitive and social theories that help clarify and provide explanation for the engagement in bullying behaviors. When school personnel understand the theoretical explanations that underlie bullying behaviors, logical, effective interventions can be developed. This next section will provide a brief overview of relevant cognitive and social theories that help explain social behaviors among students.

Social Information Processing Theory

Social information processing (SIP) is one of the most widely utilized theories to describe children's social and emotional functioning (Crick & Dodge, 1994; Dodge & Crick, 1990; Dodge et al., 2003; Shahinfar, Kupersmidt, & Matza, 2001). SIP suggests that individuals' unique biological composition, along with memories of previous experiences, impacts their interpretation of current experiences and is causally related to behavioral functioning (Crick & Dodge; Dodge & Crick). SIP consists of six components that include (1) encoding of external and internal stimuli, (2) mentally interpreting these stimuli, (3) selecting a specific goal, (4) constructing a certain response, (5) making a decision, and (6) engaging in a behavioral and/or emotional response (Crick & Dodge; Lemerise & Arsenio, 2000).

Theory of Mind

Theory of mind (ToM) has been defined as the ability of people to attribute mental states to themselves and others in order to explain and predict behavior (Premack & Woodruff, 1978; for a recent review, see Taylor, 1996). Operationally, ToM is divided into many developmental tasks, such as understanding of false beliefs, recognition of complex emotions, empathy, understanding of faux pas, and recognition of deception (Happé, 1994). ToM is essentially the ability to engage in higher order perspective-taking.

Theory of Homophily

The homophily hypothesis states that people who are similar to one another on the basis of certain attributes tend to associate with one another (Kandel, 1978). Homophily is divided into two components: (1) selection and (2) socialization (Kandel; Hogue & Steinberg, 1995). *Selection* refers to the tendency to choose friends on the basis of preexisting similarities. *Socialization*, on the other hand, refers to the tendency for similarity to increase as peers shape one another's behavior over time.

Dominance Theory

While homophily theory suggests that "birds of a feather flock together," dominance theory purports that the need to be "top dog" is related to social functioning. When attempting to understand children's social functioning, adults must understand their peer relationships in combination with their personality (Fleming, 1949). Dominance theory has guided empirical investigations of social relationships with regard to bullying and victimization, and it has helped explain why bullying behaviors peak in middle school (Pellegrini, 2002).

Attraction Theory

Another theory that has explanatory power for understanding bullying is attraction theory. Attraction theory explains perceived similarities between individuals and explains the general feeling of attraction between individuals

(Bukowski, Sippola, & Newcomb, 2000; Levy, O'Neal, Taylor, & Langley, 1990; McCormack & Smith, 1974; Moffitt, 1993; Shuntich, 1976). Byrne (1971) believed two individuals with similar attitudes and values are "attracted" to each other, as their perceived similarity decreases the likelihood for conflict. Shuntich found that students who were attitudinally similar to the each other liked the similar person significantly more and were significantly less aggressive toward that person compared with dissimilar students.

Social Learning Theory

Social learning theory posits that behavior is determined by the reciprocal interaction between cognitive, behavioral, and environmental influences (Bandura, 1977). This triadic reciprocity suggests that the person and the environment do not function independently, but instead, determine each other (Bandura, 2004). One of the most salient components of social learning theory is vicarious learning (i.e., modeling). Vicarious learning plays a large role in the future behavior of individuals (Bandura, 1977). In addition to observing behavior, individuals also encode the consequences of the behavior, thereby learning when and how to use the new behavior. Thus, individuals weigh the costs and benefits of engaging in a certain behavior (or not). Therefore, not all learned behaviors are used; rather it depends upon the factors that activate the behavior and the environmental conditions that sustain the behavior (Tedeschi & Felson, 1994).

Social Ecological Theory

Thus far, the theories reviewed relate to the individual (SIP, ToM), to peer group functioning (homophily, dominance, attraction), and to the interaction between the individual and other people (social learning theory). One unifying theory that encompasses the individual and the multiple contexts in which individuals function is social ecological theory. Social ecological theory is based on the assertion that the outcome of a given behavior or event is a result of the individual in relationship with the broader environment (i.e., family, peer group, classroom, school, community, culture, etc.; Bronfenbrenner, 1979). Social ecological theory is the only theory about bullying that specifically includes culture as a component of bullying.

Cultural Differences in Definitions, Prevalence, and Beliefs about Bullying

In a study of English and Swedish secondary students, a significantly larger percentage of English students believe that "calling someone names" is a form of bullying, whereas Swedish students did not. Conversely, a significantly higher percentage of Swedish students perceive that "leaving someone out of a group" can be categorized as a bullying behavior, while English students did not (Boulton, Bucci, & Hawker, 1999). Interestingly, both of these forms of bullying can be categorized as relational bullying; however, there was significant definitional discrepancy across cultures.

Similarly, Cerezo and Ato's (2005) study also found cross-cultural differences in a similar criterion for bullying, "Leave someone out of activities and games," posed in the above-mentioned study. This study looked at differences and similarities in bullying in middle school students in Spain and in England. This question was statistically significant for the students in Spain, but was not for the students in England, indicating a difference in definition across cultures. In a large study across 14 countries looking at definitional differences in the construct of bullying, researchers found that while differences across age were evident as to which activities constituted bullying, definitions of bullying remained relatively consistent across countries (P. K. Smith, Cowie, Olafsson, & Liefooghe, 2002).

Perhaps as a result of the differences in students' beliefs as to which behaviors compose bullying, prevalence rates also differ across countries. Recent studies conducted with English students illustrated a higher percentage of involvement in bullying than in other countries. On the whole, German students reported a relatively low frequency of bullying as compared with English students. In a study of 6- and 8-year-olds in England and Germany, 24% of English students reported being bullied weekly, whereas only 8% of German students reported this frequency. However, 2.5 to 4.5% of English students reported their role as being a bully, and 9.5% of German students reported this same role (Wolke, Woods, Stanford, & Schultz, 2001).

Menesini et al. (1997) conducted a study analyzing the prevalence rates of bullying among Italian and English primary and secondary school students. They found that 40% of Italian primary and 28% of Italian secondary school students reported being bullied "sometimes or more" in a school year, a percentage nearly twice as high as reported by the English students (Menesini et al.).

Recently, researchers have begun to look at reports of rates of bullying in relation to ethnicity and race. A study that examined seventh- and eighth-grade self-reported bullies and victims found no significant difference in involvement based on ethnicity (Seals & Young, 2003). Another study also found no significant difference between African American and Caucasian students regarding different types of bullying students were engaged in (verbal, physical, etc). Similarly, Kaufman et al. (1998) found that ethnicity was not as significant a factor in bullying as gender and grade level. Wolke et al. (2001) found similar results in

their study of a younger population of 8-year-olds, finding ethnicity did not have a significant association with bullying interactions.

As evidenced by the definitional differences and varying prevalence rates of bullying across cultures and countries, some students appeared to hold culturally divergent beliefs about bullying as well. In Menesini et al.'s (1997) above-mentioned study, 48% of Italian students in primary grades and 60% in secondary grades reported that involvement in bullying "upset me a lot." Although English students reported higher prevalence rates of bullying, they also appeared to have reported less emotional impact, with 26% of English primary students and 12% of secondary students endorsing this same feeling (Menesini et al.).

In an Australian study, however, researchers found that both ethnicity and sex differentiated students attitudes toward bullying. Ethnic minorities placed greater importance on attributes proposed as consequences of bullying. No ethnic differences were found, however, for incidence of involvement in bullying, nor were there any differences found between ethnicities regarding attitudes toward bullying interventions (Nguy & Hunt, 2004).

Theory-Based Research

In the preceding section, we laid the theoretical framework for understanding social and cognitive theories that explain facets of human behavior. In this section, we will examine some of the empirical literature that has looked at bullying and victimization from these seven perspectives.

Social Information Processing Theory and Bullying

SIP researchers have found that aggressive children experience errors in social information processing, including (1) cue encoding, (2) cue interpretation, (3) response generation and selection, and (4) enactment (Dodge, 1986; Dodge, Pettit, McClaskey, & Brown, 1986; Feldman & Dodge, 1987; Milich & Dodge, 1984). In the case of engagement in bullying behaviors, at the cue encoding stage, bullies tend to seek fewer social cues before making hostile attributions regarding the intent of others (Dodge; Milich & Dodge). This often leads to a "misread" of both intent and environment. Research has identified that during cue interpretation, children who are aggressive utilize a hostile attribution bias regarding the behavior of others (Dodge; Dodge et al.). At the response generation phase of SIP, aggressive children have been found to identify more aggressive and fewer assertive responses than their nonaggressive peers (Dodge; Feldman & Dodge). In the enactment phase, Dodge et al. also identified that aggressive children lack the skills to enact competent responses to negative situations. Thus, the social information processing that occurs in students who bully others differs significantly from that in students who do not bully others. SIP theory provides a way of understanding how thinking processes are related to behaviors such as bullying.

Theory of Mind and Bullying

Theory of mind also explains how some bullies are so adept at bullying that adults may not notice these behaviors. The role ToM plays in bullying has been the subject of recent scholarly debate, generating two divergent views. On the one hand, Sutton, Smith, and Swettenham (1999b) discovered that children categorized as "ringleader" bullies appear to have superior ToM skills. On the other hand, Crick and Dodge (1999) indicated that the historical trend in research has identified an inverse relationship between perspective-taking abilities and aggressive behavior. What emerges from this debate is a heterogeneous view of bullies—one that accounts for both the bullies who have strong ToM skills and those who do not (Sutton, Smith, & Swettenham, 1999a; 1999c; 2001).

Sutton, Smith, and Swettenham (1999b) utilized ToM to define social cognition within the context of bullying. They had participants read 11 short stories designed to test understanding of mental states or emotions. Based on their results, they proposed that bullies may perceive and interpret social cues accurately, while displaying limitations with their abilities to select prosocial goals and generate positive response strategies and decisions. These observations could reflect past experiences and strategies that have been effective for gaining social status or social resources. This view represents bullying as a complex, functional behavior rather than a skill deficit, which is consistent with some evolutionary models of aggression (Hawley, 2003).

Happé and Frith (1996) evaluated the performance of 6- to 12-year-old children diagnosed with conduct disorder on false belief tasks. All of the children with conduct disorder passed the ToM tasks, though they demonstrated social deficits on an observational measure. Data have also indicated that relational methods of bullying increase with age (Rivers & Smith), that girls rely more on relational strategies when they bully (Bjorkqvist, Österman, & Kaukiainen, 1992; Rivers & Smith, 1994), and that girls perform better on ToM tasks than boys do (Baron-Cohen & Hammer, 1996). As a result, it is believed that ToM skills are more highly developed in individuals who utilize relational techniques

to bully because they must understand and manipulate an entire social system. Bullying also represents a type of social interaction that can provide experiences that may develop social cognition in bullies, victims, and bystanders. Each individual involved in a bullying interaction might assume a specific and ongoing social role. Following each interaction, the bully's social status may advance while the victim's diminishes. These interactions could also reflect another predominant finding that aggressive children demonstrate a lack of empathy (Bjorkqvist, Österman, & Kaukiainen, 2000). While ToM is a useful theory to describe the manipulative qualities of some bullies, it does not explain the group phenomenon associated with some bullies. To understand these group dynamics, we turn to the theories of homophily, dominance, and attraction.

Theory of Homophily and Bullying

The homophily hypothesis has been used to explain within group similarity with respect to many types of externalizing behavior, such as antisocial behavior (Kiesner, Cadinu, Poulin, & Buccci, 2002; Kiesner, Poulin, & Nicotra, 2003), drug use (Kandel, 1978), and aggression (Espelage, Holt, & Henkel, 2003; Xie, Cairns, & Cairns, 1999). In general, adolescents tend to associate with friends who display the same behaviors and those behaviors tend to increase over time within the peer group.

Espelage et al. (2003) investigated peer influence on bullying behavior (e.g., teasing) and overt physical aggression (e.g., fighting). Significant within-group similarity was found in regard to both forms of self-reported aggression. This suggests that students who engage in bullying and/or fighting tend to associate with peers who also exhibit such behaviors. Finally, in conjunction with previous research on aggression, bullying tended to increase among peer groups who reported bullying others.

Salmivalli, Huttunen, and Lagerspetz (1997) also found a relationship between peer group affiliation and participation in bullying as either a bully, a reinforcer, an assistant, or a victim. Specifically, participants who endorsed bullying behaviors tended to affiliate with other participants who endorsed the same behaviors. Interestingly, the size of the peer group differed between the groups in that victims tended to have smaller peer groups, while bullies, reinforcers, and assistants tended to form larger peer groups. Furthermore, participants who were outside the peer group tended to be victims. Thus, bullying behavior may be influenced by group formation.

Homophily results in groupings of students based on many characteristics, one of which is social status. T. W. Farmer and E. Z. Farmer (1996) demonstrated that well-defined social structures exist in classrooms and that students tend to belong to clusters in which they share similar attributes. Although research is beginning to suggest that gender differences in bullying may not be as clear as was previously thought, research indicates that popular males tend to be more aggressive and popular females tend to exclude others who are unlike them (Adler, Kless, & Adler). Swearer and Cary (2003) found that both victims and bullies reported being "different" as the reason for either being bullied or bullying others. Therefore, dominant peer groups are formed that physically or relationally reject those who are different, which leads to less social support for victims of bullying. The homophily hypothesis suggests that if left alone, incidents of bullying would increase as groups of bullies become more similar through homophily and through the need to establish dominance.

Dominance Theory and Bullying

Peer affiliation has been shown to be a strong factor in mediating bullying and victimization (Mouttapa, Valente, Gallaher, Rohrbach, & Unger, 2004; Pellegrini & Bartini, 2000; Pellegrini, Bartini, & Brooks, 1999). It is during the transition from elementary school to middle school that bullying behavior may peak, ebbing and flowing as necessary to establish and maintain dominant peer relationships. In a longitudinal study conducted by Pellegrini and Long (2002), researchers found that bullying and aggression initially increased with the transition to middle school, and then declined as dominance was established. Further, Long and Pellegrini (2003) found that bullying covaried with dominance during the middle school years, showing that when bullying increased, dominance increased and when bullying decreased, dominance decreased. These findings are consistent with dominance theory in that individuals are ordered in a hierarchy (i.e., toughest to weakest) according to their access to resources and once the hierarchy is established, aggression deceases because individuals know who is most dominant (Pellegrini, 2002; Pellegrini & Bartini, 2001).

Attraction Theory and Bullying

Moffit (1993) stated that during that transition from childhood to adolescence, antisocial youth move from the fringes of the social group to a more powerful, visible status role. Moffitt further explained that adolescents often begin to engage in "social mimicry," in which adolescents adopt what are now seen as "successful behaviors." In this situation, adolescents who have not previously shown aggressive tendencies may begin to display aggressive behavior, as it is now being reinforced and valued by peers.

Similar to Moffitt's (1993) explanation of this increase in aggression from childhood to adolescence, Bukowski et al. (2000) defined attraction theory as youth desiring affiliation with peers demonstrating independent behaviors and avoidance of peers engaging in more prosocial behaviors. This desire for independence and more "adult" behaviors appears to be most prominent during the transition from childhood to adolescence.

In a study conducted with 217 students transitioning from elementary to middle school, Bukowski et al. (2000) confirmed this increase in attraction to aggressive classmates. They discovered boys nominated as attractive by their female classmates had aggression scores two-thirds of a standard deviation above the mean (Bukowski et al.). The authors discovered a significant difference between aggressive children attracted to peers displaying aggressive behaviors, and the attraction scores of children attracted to less aggressive peers.

In sum, attraction theory posits that aggressive children are viewed as "attractive," or well liked, by both aggressive and nonaggressive peers. Thus, students identified as bullies by their peers may appear more attractive as potential friends and more powerful than students who engage in low-aggression behaviors (e.g., pure victims or bystanders of bullying). These findings suggest that students categorized as "attractive" (e.g., physically attractive, attitudinally similar) are less likely to be bullied than "nonattractive" students (Garbarino & deLara, 2002).

Social Learning Theory and Bullying

In addition to the general theory of human behavior, Bandura (1978) applied social learning theory specifically to aggression. Bandura explained that vicarious or observational learning allows people to develop large behavioral repertoires of aggressive behavior, as opposed to learning through direct experience and trial and error. The actual response depends on the interpretation of the source, the learned responses, and the potential consequences. Maintenance of the behavioral response depends on anticipated positive consequences. In sum, vicarious learning leads to a large repertoire of behaviors, aversive stimulation leads to the activation of potential responses, and one particular response is chosen based on the perceived potential of positive consequences. Depending upon the learning history of the individual, aggressive or nonaggressive behaviors will be chosen.

While much of the research on social learning theory has focused on aggression, no current study has directly linked social learning theory and bullying. Many of the aggression studies, however, do investigate both relational and physical aggression. Tapper and Boulton (2005) used social learning theory to investigate the consequences of direct and indirect forms of aggression based on responses of the victim(s) and the bystander(s). Participants were observed using a micro video camera for a period ranging from 40 to 105 minutes. The observers then coded instances of aggression and the responses of the victim and the peers. The results indicated that the most common consequences of direct aggression were retaliation and victim withdrawal. On the other hand, peer support for the aggressor was most likely to occur when the aggression was either relational (indirect or direct) or indirect verbal aggression.

Hall, Herzberger, and Skowronski (1998) studied outcome expectances and the outcome values of aggressive behavior. Hall and colleagues suggested that aggressive children have certain expectations about the consequences of their behavior and attach value to those outcomes. Participants read stories in which a peer provoked them; one story asked them to imagine verbally retaliating and one asked them to imagine physically retaliating. They then measured the likelihood of physically and verbally retaliating and the outcome values attached to their choice. The results suggested that children high on self-reported aggression were less likely to expect being punished or to feel bad; rather, they expected to gain peer respect as a result of aggressive acts. Children who were more likely to expect being punished and/or who cared more about punishment scored lower on self-reported aggression. These studies provide some explanatory power for the engagement in bullying behaviors: Bullying is a learned behavior that is reinforced in many peer groups and settings (Garbarino & deLara, 2002).

Social Ecological Theory and Bullying

Given that bullying is not an isolated phenomenon, social ecological theory has been applied to the conceptualization of bullying behaviors in an effort to more fully understand its perpetuating cycle (Garbarino & deLara, 2002; Newman, Horne, & Bartolumucci, 2000; Olweus, 1993a; Swearer & Doll, 2001). Olweus (1997) pointed out research evidence which suggested that individual characteristics, as well as environmental factors (i.e., teacher attitudes, routines, etc.), play a major role in determining the extent to which bullying behaviors will manifest either in a classroom or in a school. This evidence also dispelled the myth that victimization is "caused" by external attributes of the individual, such as having red hair, wearing glasses, or being overweight.

The microsystem is defined as the *immediate setting* containing the individual and its influence on that individual. Examples of this may be the home or school and what influences each has on the child or student. The second level, the mesosystem, is seen as the *interrelations* among major settings or interactions between microsystems. Specific to bullying, an example would be the interrelations between home and school, as well as between peer groups, in terms of responses to and attitudes toward bullying behavior. The exosystem consists of *social structures* in which the individual may not specifically participate, but which have an influence on the individual (i.e., school policies, state legislation on bullying, etc.). The fourth system is the macrosystem. The macrosystem differs in that it does not refer to a specific context affecting the individual, but instead refers to general patterns for structures occurring at the other levels. Examples might be school or classroom structures (e.g., physical arrangement or layout) or societal and/or cultural attitudes toward bullying and victimization (Bronfenbrenner, 1977; Swearer & Espelage, 2004).

Bullying and victimization can be conceptualized as encompassing all contexts in which individual characteristics interact and are reciprocally affected by multiple contexts, factors, and interchanges. Of particular interest to the study of bullying behaviors within schools are the contexts of the family, school, community, and culture and their interchange with and influence on the individual student (Swearer & Doll, 2001). Given methodological and monetary constraints, few studies have attempted to examine bullying from a social ecological framework. One attempt to test a social ecological model found support for individual and school factors as salient in a social ecological framework (Swearer et al., 2006).

Theory-Based Practice

The IOM framework for prevention, treatment, and maintenance efforts to prevent bullying will be described, taking into account developmental differences across the school years. Areas of innovation will be discussed, including best practices in bullying prevention and intervention that emphasize home–school connections.

Best practices in bullying prevention involve schools first implementing Reynolds' (1986) three-stage multiple-gate screening procedure to identify youngsters who are at risk for bullying in school settings: (a) conducting large-group screening with self-report bullying measures; (b) 3 to 6 weeks later, retesting students who, on the basis of the large-group screening in Stage 1, meet cutoff score criteria for bullying and/or victimization; and (c) conducting individual, clinical interviews with students who manifest clinical levels of bullying and/or victimization at both Stage 1 and Stage 2 evaluations. Effective treatment of bullying typically includes schoolwide efforts augmented by individual therapy. Effective maintenance includes monitoring

Table 40.1 Bullying Prevention and Intervention Programs: Prevention, Treatment, and Maintenance

Intervention Name	Grades Intended	Targeted Behaviors/ Goals	Available Outcome Studies	IOM Spectrum
Bully Busters	K–8	Reduce & prevent bullying; increase teacher knowledge and skills	Newman-Carlson & Horne, 2004	Prevention, Treatment, & Maintenance
Second Step	Pre/K–9	Increase prosocial skills; decrease aggression	Frey et al., 2000; McMahon & Washburn, 2003; Sprague et al., 2001; Taub, 2002	Prevention & Treatment
Olweus' Bullying Prevention and Intervention Program	3–12	Reduce & prevent bullying; improve peer relationships	Carey, 2003; Endresen & Olweus, 2001; Eslea & Smith, 1998; Kallestad & Olweus, 2003; Kristensen & Smith, 2003; Olweus, 1991, 1992, 1993b, 1994, 1995a, 1995b, 1997a, 1997b, 1997c, 2003, 2004	Prevention & Treatment
Expect Respect	K–12	Prevent bullying and sexual harassment; create positive school climate	Meraviglia et al., 2003; Rosenbluth et al., 2004; Sanchez et al., 2001	Prevention & Treatment
Steps to Respect	3–6	Prevent bullying; improve peer relationships; increase bystander intervention	Frey et al. (2005); Hirschstein & Frey (2006)	Prevention

compliance with long-term goals, reducing bullying, and conducting ongoing evaluations to monitor progress.

This section reviews several available bullying/victimization intervention programs. While the included interventions and numerous other programs have been implemented in hundreds—perhaps even thousands—of settings, limiting the programs presented here to intervention with theoretical support and published evaluations of program effectiveness reduced the choices to a small handful (see Table 40.1). The following intervention programs were chosen because they are nationally or internationally recognized and have presented published, empirical evaluation data. This list is not intended to be exhaustive, but the published studies on which we relied here are readily available to the research and professional community. This information regarding the effectiveness of the interventions seems critical in that it allows both researchers and practitioners to enter into the bullying intervention realm with reasonable confidence that we can observe our critical professional commitment: to do no harm.

The Olweus Bullying Prevention Program

Dan Olweus, a Norwegian psychologist, developed and implemented the Olweus Bullying Prevention Program in Norway in the mid-1980s (Olweus, 1991). His program is among the most established and is probably the most widely applied intervention, both in Europe and in the United States. He developed this comprehensive intervention in response to the suicides of several Norwegian children associated with school bullying. These highly publicized deaths had a large impact in a small country such as Norway (population of ca. four million) and helped generate support for Olweus' large-scale, school-based efforts to intervene. The Olweus program has also spawned a number of notable intervention programs based on Olweus' work that will not be specifically discussed here due to space limitations (e.g., Pepler, Craig, O'Connell, Atlas, & Charach, 2003).

Theoretical/conceptual basis. Conceptually, Olweus has placed his intervention efforts within a larger philosophy that stresses the fundamental democratic right of students. Within a developmental perspective, Olweus has presented some degree of detail on his views of the causes of bullying, and he has maintained that bullying behavior is fostered by an interaction between parenting styles/behaviors (e.g., lack of warmth and involvement, permissiveness of aggressive behavior, and power-assertive discipline), the larger social environment (e.g., teacher attitudes and routines that tolerate or permit bullying), and children's temperament (e.g., highly active, easily emotionally aroused children are more likely to be aggressive). Victims, in Olweus' view, are characterized primarily by socially withdrawn behavior. Olweus' parent interviews have also indicated that victims tend to display higher levels of cautious and sensitive behaviors from early age, perhaps indicating temperament as a causal factor. He made no assertions as to parenting behaviors that may be related to victim status.

Contrary to the beliefs of many psychologists, Olweus dismissed anxiety and insecurity as causal factors in bullying behavior. He also maintained that the bullying risk factors above are unrelated to children's socioeconomic status. Additionally, he has attributed *increases* in bullying behavior to factors originating within children's social interactions such as social contagion, a weakening of inhibitions against aggressive behavior, diffusion of responsibility for bullying among the group, and changes in both bully and group perceptions of the victim. In a related focus on the larger social environment, Limber, Nation, Tracy, Melton, and Flerx (2004) cited the Olweus program as based on ecological theory and emphasizing related goals such as creation of a warm and caring school environment characterized by consistent involvement of adults in students' experiences, firm limits on student behavior related to bullying and victimization, and nonhostile/nonphysical consequences for violations of behavior standards.

Intervention components. Olweus' (1993a, 1993b, 1997) intervention efforts, following his conceptual tenets, focused on individual components (e.g., talks with bullies, victims, and parents; detailed individual intervention plans), as well as school-level components (e.g., adequate supervision of recess, staff discussion groups) and classroom level interventions (e.g., explicit antibullying rules, class meetings about bullying problems). The Olweus program has been implemented and evaluated relatively extensively in Norway and Europe, as well as in the United States. A thorough presentation of those findings is well beyond the scope of this chapter, and this section will focus on the American implementation as carried out by Limber and colleagues (e.g., Limber, Nation, Tracy, Melton, & Flerx, 2003; Olweus, Limber, & Mihalic, 1999).

Schoolwide components. This intervention program was implemented within 18 South Carolina middle schools (data below are from six schools completing two years of the study and six schools completing one year). The original Olweus program was modified to include schoolwide (as opposed to classroom-level) antibullying rules and broadened to involve the larger community. In the school year prior to the study, baseline data on bullying prevalence, student attitudes, and so forth was collected. The following August, one-day, schoolwide trainings occurred prior to the start of school, and staff discussed baseline data and subsequent implementation plans. Then, schools held a school-

wide special event (e.g., school assembly) to announce the program and its components to the students. The school staff also developed, announced, and enforced their own versions of schoolwide antibullying rules based on Olweus' (1993b) framework. The three basic guidelines were

1. We will not bully other students.
2. We will try to help students who are being bullied.
3. We will make a point to include students who are easily left out.

Staff also increased their monitoring of student behavior at empirically identified "hot spots" for bullying. Typical areas included recess/playgrounds, lunchrooms, hallways, bathrooms, and bus loading/unloading areas. School staff also developed school-specific programs for rewarding students who displayed prosocial behavior, for example, with tokens for redemption at the school store or entry into drawings for prizes.

Classrooms. The component was a class meeting held a minimum of every 2 weeks (20–30 minutes per session) to discuss bullying and peer relations. Many teachers led discussion of bullying prevalence and also used a video made available by program staff. Some meetings also included role playing, creative writing, and art projects to address the topic. Mental health support staff (either local, school-based personnel or graduate students provided by the program) were made available to assist teachers in conducting meetings and to help those uncomfortable leading such meetings.

Bullies and victims. Bullies and victims were also provided with individual-level support services and response protocols. Bullies were made immediately aware of their behavior by adult feedback, including disapproval and appropriate sanctions. Victims were protected from the aggressive behavior and given support in developing social skills and friendships. Adults were encouraged to directly intervene in all bullying episodes they witnessed and to engage support staff in resolution of the situations and subsequent monitoring.

The broader community. Parent and community involvement was also promoted. Parents were notified of the program via pamphlets and the program was also announced at PTA and parent–teacher meetings. Some schools presented more extensive information to parents via panel discussions and special events. Community organizations and media were encouraged to announce the program and raise community awareness of the issues.

Implementation fidelity. Limber and colleagues (2003) indicated that implementing some critical areas of the intervention components were a challenge for some schools and teachers. Challenging areas included maintaining the level of staff commitment to the program, maintaining high levels of involvement of staff over time (e.g., viewing the intervention as a 1-year effort rather than as systematic change), and teacher difficulty in holding classroom meetings.

Evidence Base. Research has indicated that the Olweus program has been successful in reducing levels of bullying and victimization in schools. The program evaluation data from Norwegian interventions (Olweus, 2003) indicated consistently lower levels of bullying and victimization and general antisocial behavior (including bullying) across early adolescent age groups. The American studies (Limber et al., 2003; Olweus et al., 1999) indicated consistently positive results, but with a somewhat lower magnitude of school-level effects relative to the Scandinavian studies. Significant reductions in bullying behaviors were generally strongest at year 1 follow-up (as opposed to year 2 follow-up) and indicated relatively large drops in bullying behavior for boys and girls. Findings from self-reports of victimization and of social isolation indicated a significant decrease for boys, but not for girls. Students also reported fewer incidences of bullying to parents. The authors maintain that the pattern of stronger and more consistently positive effects for boys over girls may be the result of the type of bullying/victimization addressed, with a relatively stronger or more effective emphasis on overt physical and verbal forms of aggression more typical in boys (as opposed to indirect forms of aggression that tend to occur more often with girls).

In sum, results indicate that the Olweus program is effective with early adolescent age groups, particularly for boys and/or direct forms of aggressive, bullying behaviors. The focus on school level variables precludes producing some data on the efficacy of the intervention relative to classroom and, especially, individual level effects. More fine-grained follow ups of the program effects are needed to contribute to a detailed understanding of the intervention efficacy in different types of classrooms and for the range of bullies and victims, especially with regard to gender differences.

Second Step

Second Step (Committee for Children, 2005) is a comprehensive violence prevention program developed by the Committee for Children and is one of the most extensively researched violence prevention programs available. To date, Second Step has been employed in the United States, Canada, Australia, Germany, New Zealand, Norway, and the United Kingdom. Second Step has also developed a

Spanish language version. Currently, Second Step is also the only program reviewed here that has curricula designed to serve pre-K through 4th grade (the other programs discussed here have been applied in ca. 5th to 8th grades).

While Second Step was not specifically designed as a bullying and victimization intervention, it does target direct and relational aggression. The primary focus of Second Step is to develop students' social-emotional skills in four areas: (1) empathy, (2) impulse control, (3) anger management, and (4) problem solving (Committee for Children, 2005). Frey, Hirchstein, and Guzzo (2000) suggested that competencies in these four areas serve as protective factors against problem behavior and peer relationship difficulties.

Theoretical basis. Second step is grounded in social learning theory (Frey et al., 2000). There is an emphasis on modeling, self-reflection, execution, and reinforcement. These constructs are considered necessary to the development and continued use of the specific skills taught through Second Step. The Committee for Children (2005) contends that aggressive children are at higher risk for more serious behavioral and emotional problems and that by providing direct instruction of specific skills and the opportunity to practice them, aggressive behaviors will decrease and positive social interactions will increase.

Though not explicitly framed as such by the authors, Second Step may also be conceptualized from an ecological systems perspective (Bronfenbrenner, 1979), similar to the Olweus program. Second Step is administered in a group format, typically within a classroom, and the authors also recommended that the program be implemented across all classrooms in a school. Frey et al. (2000) suggested that when this occurs, students are more likely to develop skills and maintain the program effects. Finally, at the family level, Second Step has developed a Family Guide for parents of students from preschool to fifth-grade ages.

Intervention Components. The Second Step program delivers content primarily through regularly scheduled, teacher-led lessons within small groups or at the classroom level.

Teachers. Teacher training is a universal component of the Second Step curriculum at all grade levels. Through a sequence of training sessions, teachers are instructed in how to model skills during student lessons. Throughout the program, positive reinforcement of skill use is also stressed. Students are then taught specific prosocial skills, which they then practice on a regular basis. Teachers generally conduct one to two 30-minute lessons per week with their students.

Elementary students. In the elementary curriculum, students practice prosocial behavior skills under the supervision of the teacher. Teachers follow the lesson plan, which includes lesson objectives, a script, discussion questions, role-plays, or other activities. With younger children, colorful puppets are sometimes are used to model problem solving and skill use. The plan also includes suggestions for modeling the skills throughout the week. (Committee for Children, 2005).

Middle school students. The middle school curriculum teaches students higher level skills and places more emphasis on changing attitudes and beliefs about aggression. The curriculum includes age-appropriate literature with relevant content. Lessons and discussions encourage students to try to understand characters' points of view and actively promote the development of perspective taking skills. Middle school students also engage in role plays and related discussion activities relevant to their daily experiences.

Evidence Base. As previously mentioned, Second Step provides a relatively strong degree of empirical evaluation, and a detailed review of all studies is beyond the scope of this chapter. The chapters in this review all included some form of teacher training prior to implementation of the program and were selected in order to be representative of the wide span of grade levels for which Second Step was designed. Studies summarized here include Sprague at al. (2001; grades K–8), Grossman et al. (1997; grades 2–3), Taub (2002; grades 3–5), and Van Shoiack-Edstrom, Frey, and Beland (2002; grades 6–8).

Sprague and colleagues (2001) conducted the most comprehensive analysis of the Second Step program by assessing its effects at all grade levels for which data were available at the time. This study did not, however, investigate the Second Step effects in isolation, but instead as part of a whole school program that involved the creation of new school rules as well as a schoolwide positive reinforcement and discipline program in addition to the Second Step curriculum. Sprague et al. measured their effectiveness with office referral data, perceptions of school safety, perceived behavioral support, and declarative knowledge of the Second Step curriculum. While an analysis of the unique effects attributable to the Second Step curriculum was not possible, findings indicated that students' declarative knowledge of the Second Step program components increased slightly (from 46% to 55%). Unfortunately, the authors did not administer the same tests to the control groups and could not rule out the role of maturation effects as a component of the increase. The analyses also indicated a decrease in office referrals for both middle school and elementary school participants (−82% and −51%, respectively), while the middle school control groups displayed a corresponding increase (82%) and elementary school con-

trols presented only a slight increase (7.5%). The authors found no differences in changes in perceptions of school safety between the intervention and control school.

Grossman et al.'s (1997) analysis of the Second Step program included data from 12 schools serving similar socioeconomic and ethnic populations (6 intervention groups and 6 control groups). The Second Step curriculum was implemented with second- and third-grade students across the intervention groups. Observational data was collected on aggressive behaviors prior to intervention, directly following intervention, and 6 months after intervention. Grossman et al. found that physical aggression for the intervention group decreased, whereas these behaviors increased for the control students. This study is remarkable in the use of observational data and may provide some of the strongest evidence published indicating a decrease in aggression for intervention groups.

Taub (2002) evaluated the effectiveness of Second Step with third- to fifth-grade students in a primarily Caucasian, low SES, rural school context. Taub collected pre- and postintervention data and conducted a 1-year follow up. Teacher ratings of student behavior were gathered on three indices: "responds to directions from adults, engages appropriately with peers, and follows classroom rules" (p. 189) and two negative behaviors: "bothers/annoys/distracts other students and fights/argues with peers" (p. 190). Taub's findings indicated that intervention students displayed a decrease in antisocial behavior while the control school displayed an increase. Interestingly, the behavioral observations revealed a decline in observed prosocial behaviors for both schools; however, the decline was more severe for the comparison school than it was for the intervention school.

Van Shoiack-Edstrom et al. (2002) expanded the Second Step curriculum from one year duration to three years with groups of sixth- to eighth-grade students in the United States and Canada. The accompanying evaluation study used data gathered from the first 2 years of the program. The authors assessed intervention effectiveness by measuring student endorsement of aggression, verbal derogation, and social exclusion items. Additionally, they gathered data on students' perceived difficulties performing the adaptive social skills. This evaluation was also the only study in this review to include explicit measures of relational aggression. In year 1 of their study, the authors found no changes in the levels of social exclusion from pre- to postintervention, while the control group had a significant increase in social exclusion. Across the second year of the program, treatment groups showed a significant decrease in physical aggression, verbal derogation, and social exclusion, while control groups displayed either increased levels or displayed no change.

Second Step represents a broadly applied, highly visible intervention. While the targeted skills and behaviors extend well beyond bullying, per se, it is clear that the evidence supports contentions that the program should reduce bullying and victimization rates as well. Second Step is also the only program spanning early childhood and adolescent age groups and, as such, represents the only intervention program with an explicitly developmental framework.

The Expect Respect Program

While less visible than the Olweus program or Second Step, the Expect Respect program (Meraviglia, Becker, Rosenbluth, Sanchez, & Robertson, 2003) has also achieved recognition as a strategy with some empirical evaluation. The creators of Expect Respect based their intervention design on Olweus' program and research (Olweus et al., 1999); for their specific intervention components, they relied on Stein's Bullyproof program (Sjostrom & Stein, 1996). They developed their program to address traditional forms of bullying behavior, but also included a focus on bullying behaviors associated with sexual abuse and harassment. While these behaviors certainly fall under the standard definition of bullying, Expect Respect is notable for including the problems of sexual abuse and harassment as a central component of their program. The published intervention study was implemented once over the course of one school year in fifth-grade classrooms across six schools in the late 1990s in Austin, Texas.

Theoretical/conceptual basis. The program authors (Meraviglia et al., 2003; Rosenbluth, Whitaker, Sanchez, & Valle, 2003) do not explicitly cite or create a larger conceptual framework or causal model in their reports, aside from citing the work of Olweus et al. (1999) and the program developed by Stein (Sjostrom & Stein, 1996). They located their efforts within a larger context of violence prevention (the program, not coincidentally, was developed through a grant to a sexual and domestic violence prevention services provider). The authors stated that child contexts that tolerate bullying behavior foster increased aggressive behaviors and violence in adulthood and thus contribute to the incidence of sexual harassment and domestic violence, but do not explain specific processes via which this would occur. The intervention targets increasing bystander intervention as the behavioral means for decreasing bullying behaviors. The project "targeted the involvement of all members of the school community in recognizing and responding effectively to bullying and sexual harassment among students" (Rosenbluth et al., p. 212). The authors did not cite prior theoretical/causal models or present empirical support for the effectiveness of bystander intervention as a strategy for reducing harassing or aggressive behaviors in children.

Intervention Components. The program relied heavily on the *Bullyproof* model (Sjostrom & Stein, 1996) and presented classroom curriculum, staff training, policy development, parent education, and support services components. The program was implemented in fifth-grade classrooms (with matching control schools; see the following sections) in Texas. The students reflected the racially and socioeconomically diverse population of Austin, Texas (i.e., they included significant numbers of Hispanic and African American participants). No additional information has apparently been published on the precise number of classrooms engaged, but six program schools were involved (as well as six matched control schools), and the program involved 929 intervention students and 834 controls at the outset.

Classroom components. Twelve weekly *Bullyproof* sessions were administered in the intervention classrooms. These sessions targeted bystander intervention as the mechanism for reducing bullying and sought to increase the "ability and willingness," (Meraviglia et al., 2003) of bystanders to intervene. This increase might, in turn, decrease bullying. The curriculum also sought to aid students in distinguishing playful joking around versus hurtful teasing. Students were encouraged to "speak up or get help from an adult when they witnessed someone being mistreated" (Rosenbluth et al., 2003, p. 214) via writing assignments, role-playing, and class discussions.

Staff training. Two-tiered staff trainings were implemented by *Bullyproof* staff for project personnel. Counselors, teachers, and administrators received a single 6-hour training and other personnel (e.g., office staff, hall monitors) received 3 hours of training once per semester (i.e., twice) for the yearlong duration of the program. Staff were presented with prior research findings and were coached in intervention strategies targeting consistent staff responses across school contexts and the promotion of mutual respect among students (Rosenbluth et al., 2003). The training included discussions and activities.

Policy development. School administrators were trained to develop a policy supporting consistent staff responses to bullying and sexual harassment. Administrators were provided with a template or guideline for the development of the policies that were subsequently presented to school staff/parent advisory councils (Rosenbluth et al., 2003). Guidelines were then to be presented to staff, parents, and students with appropriate support for implementation (the authors report varied results in implementation of this component).

Parent education. Parents were provided with information through newsletters and presentations (attendance was voluntary and reported as "varying by site;" Rosenbluth et al., 2003, p. 215). The information presented related vocabulary, strategies for helping bullies/witnesses/victims, tips for responses and prevention, and described available community resources for coping support.

Support services. Counselors from the violence prevention center were made available to assist school counselors in providing support for children involved in bullying. Additional training was also provided to the school counselors themselves and included strategies for reducing victim vulnerability and alternatives to conflict resolution approaches. Counselors also received a manual on bullying, sexual abuse, dating violence, and domestic violence.

Program fidelity. The authors, throughout their publications, suggest that the fidelity of program implementation varied widely across schools and classrooms. This was especially true at the level of staff training and schoolwide policy dispersal and support. Some intervention school principals apparently did not provide significant discussion or dispersal of the policies. Two intervention schools (out of six) also declined to participate in a second year of the project.

Supporting Evidence. The project staff hypothesized that intervention students would "demonstrate greater increases in their levels of awareness of behaviors that constitute bullying . . . and sexual harassment" (Rosenbluth et al., 2003, p. 219). The authors maintained that, because of the increased awareness of bullying and so on, the intervention could logically be associated with either increases or decreases in reported bullying. It is not clear whether the authors would interpret either of these outcomes as evidence of reduced bullying problems for schools. Results supporting the program effects on bullying were extremely mixed. Control schools reported decreases in bullying behaviors, while intervention schools did not. Intervention students also reported no changes in the frequency at which they ignored bullying. Intervention students also reported an increase in witnessed bullying; it is unclear what this finding indicated (the authors attributed this to increased awareness). Both intervention and control students reported an increased intention to report bullying; however, students' reported likelihood of actually telling an adult about bullying did not change from pre- to postintervention. As the authors noted, several critical discontinuities between the stated program goals and focus and the pre- and postintervention survey items/variables that they used prevented more accurate or informative analyses from being carried out.

In sum, the evidence from the program is inconclusive as to the overall benefit to students, and the published empirical findings fall short of suggesting that Expect Respect is likely to produce reductions in bullying and associated problems for schools implementing the program. As the authors noted, the study did, however, appear to succeed in raising students' awareness of the problem—this would seem to be an important component of antibullying interventions. Perhaps future efforts at carrying out the program will provide improvements in the fidelity of implementation and will be able to more accurately assess targeted outcomes.

The Bully Busters Program

Bully Busters was developed by Dawn Newman-Carlson, Arthur Horne, and colleagues and the accompanying manuals were published in 2000 (Newman et al., 2000). Developed partially in response to Olweus' program (previously described), the authors created a program that was designed to be somewhat less comprehensive or extensive than the Olweus intervention, to be adapted to American schools, and that would still yield decreases in aggressive behavior. The results presented next were drawn from the single available journal article presenting Bully Busters and related empirical findings (Horner, Bartolomucci, & Newman-Carlson, 2003; Newman-Carlson & Horne, 2004). More detailed descriptions of the intervention, of course, can be obtained from the program manuals.

Theoretical/conceptual basis. The authors presented an unusually extensive and well-developed causal model based on Bronfenbrenner's (1979) ecological systems model and Albert Bandura's (1986) social learning model. The authors draw on the premise that environmental effects on children's behavior are transmitted through social learning/modeling and suggest that children raised in aggressive contexts (home and/or school, etc.) will be more aggressive themselves. A key component of their model is that this pattern will support children's beliefs that those who become victims deserve the treatment they receive by virtue of being weaker and, in a self-fulfilling process, because they are being victimized. Teachers, in the authors' view, play a critical role in this process in schools because they serve as models for student conduct regarding aggressive behavior in general and bullying in particular. Failure to intervene in bullying on the part of teachers is hypothesized to promote continued or increased bullying behavior.

Intervention Components. The Bully Busters intervention study was carried out by training teachers in a public U.S. middle school and was presented via collaboration with school counselors. Fifteen teachers completed the training and served as the treatment group. Fifteen of their colleagues not completing the training served as controls (they were not randomly assigned to groups). The program was implemented as a series of staff development workshops (three 2-hour workshops) with the components/modules as follows: increasing awareness, recognizing the bully, recognizing the victim, interventions for bullying behavior, interventions for victimization, prevention, relaxation, and coping skills.

Teachers were presented with training materials, participated in practice experiences, and were instructed to share the information and strategies they learned with their students. After the workshops, teachers participated in support teams that met every other week, where they problem-solved implementation of strategies and shared experiences related to their efforts to reduce bullying problems. Program fidelity was monitored through these meetings and by having teachers complete checklists on their intervention activities.

Evidence Base. Treatment and control teachers were given pre- and postintervention measures to evaluate their knowledge and use of the intervention skills, self-efficacy in dealing with problem students (e.g., disruptive, behavior disordered), and decreases in student aggression. Results indicated that the intervention group displayed significantly greater increases in skill knowledge and use and in self-efficacy in dealing with bullying related problems. The authors also reported that there was a decrease in bullying as measured by a decrease in reported referrals for aggressive behavior. An important caveat to the latter finding, however, is that the referrals measured a broad range of aggressive behaviors, including fighting, physical aggression (hitting, slapping), verbal aggression (verbal abuse), and so forth. While bullying involves these behaviors, many of them often occur outside the context of the bully/victim relationship/definition (as previously mentioned). Any reduction in students' aggressive behavior should certainly be regarded as a positive outcome, but this discrepancy reflects a common problem in the literature in that many outcome measures used tend to address aggressive behavior in general rather than identifying whether it occurs within bully/victim contexts (i.e., includes repeated interactions, involves a power differential between bully and victim, etc.).

Bully Busters, while lacking the larger implementation and empirical evaluation base of the Olweus or Second Step programs, represents a thoughtful and carefully created intervention program with thorough training and fidelity components. The level of detail the authors present regarding their conceptual/causal model and their evalua-

tion strategy is also admirable. The commercial availability of the handbooks also contributes to the usefulness of the intervention and makes it perhaps (along with Second Step) the easiest program for prospective users to evaluate prior to implementation.

Steps to Respect

The *Steps to Respect* program (Committee for Children, 2001), is a schoolwide bullying prevention program for grades 3–6. This program is designed to foster students' socially responsible beliefs, develop social–emotional skills related to positive peer relations, and increase their ability to recognize, refute, and report bullying behavior. The program also seeks to raise staff and parent awareness and responsiveness to bullying problems.

Theoretical Basis. In a recent empirical article evaluating the effectiveness of the *Steps to Respect* program, Karin Frey and colleagues (Frey et al., 2005) explicitly cited a social information processing model (Crick & Dodge, 1994) as a basis for targeting children's beliefs and goals relative to bullying , as well as their cognitive–behavioral and affective skills. The program focused on changing children's cognitions regarding bullying (e.g., recognizing bullying) and learning more prosocial methods of responding to peers involved in bullying interactions. Hirchstein and Frey (2006) reported that grades 3–6 were chosen to include the age range within which evidence suggests children's attitudes and cognitions surrounding bullying and aggression become relatively stable. The curriculum also focused on fostering a general school and home climate in which aggressive behavior was not tolerated.

This broader program focused on addressing problems across home and school contexts also seemed to support an ecological perspective (e.g. Bronfenbrenner, 1979; Olweus, 1993a). This perspective supported the program's emphasis on a whole school approach that involved those staff directly involved in student learning, as well as counselors and administrators. Furthermore, the program advocated consistent parent involvement and supported transfer of skills learned at school to the home context.

Intervention Components

Schoolwide components. School personnel were provided with an overview of the Steps to Respect core program goals and content. Teachers, administrators, and counselors, in particular, received more in-depth training on how to intervene and work with students involved in bullying in addition to training on implementing the curriculum (Frey et al., 2005). The curriculum provided models of responses to bullying behavior and guidelines for coaching students involved in the different roles within bullying interactions.

Classrooms. Students participated in literature-based classroom lessons over 12–14 weeks. There were 11 skill lessons, which focused on social–emotional skills for peer relationships, how to be a responsible bystander, and how to recognize, respond to, and report bullying (Committee for Children, 2001). The skill lessons covered topics such as the role of respect in friendships, the role of bystanders in supporting/preventing bullying, promoting empathy for bullying victims, and improving students' group entry skills. The instructional methods included direct instruction, group discussions, and skills practice/role-playing.

Community. Parents were provided with information about the program and received letters throughout the program that described the skills their children were practicing and providing ideas on how to support these skills at home (Committee for Children, 2001). All school families also received annual letters updating parents on school-specific policies and activities related to bullying and aggression.

Implementation Fidelity. Frey et al. (2005) reported high levels of implementation fidelity for their study sample, not only in classroom lessons, but also in terms of schoolwide acceptance of the program components. Teachers in the group of participating schools ($N = 6$) reported having taught nearly all (99%) of the targeted skills. Classroom observers reported good overall lesson quality and a high (92%) learning objectives completion rate.

Evidence Base. Frey et al.'s (2005) published empirical study provided evidence indicating that the program was effective in reducing—relative to control groups—observed frequencies in bullying and in producing positive changes in student attitudes and beliefs regarding bullying and aggression. The positive effects were also strongest for children showing higher levels of negative behaviors at the study onset—this would presumably be the group most schools would hope their intervention efforts would be effective within. This is the only published study we know of that used actual observations of children's playground behavior—this additional source of data strengthens confidence in the evaluation findings.

As a caveat to these results, it is important to note that in a few cases, intervention groups actually displayed small increases in undesirable behaviors or attitudes, but because this increase was not as large as that displayed by control groups, the results thus indicated positive intervention effects. This finding may indicate that the problem of reducing raw rates of bullying behavior or attitudes sup-

porting such behavior in schools is a daunting task, even for intensive intervention programs. Nonetheless, the random control trial evaluation completed here is exemplary among bullying intervention programs, and the authors' findings suggest that a program with a solid theoretical basis and good implementation practices can have positive effects on aggression and bullying in schools.

Future Directions

Synthesis

The interventions just discussed represent some of the better known efforts researchers and practitioners have made in decreasing bullying and victimization problems in schools. While evaluations of the results from their efforts are generally encouraging, it is also clear that the various program effects are not overwhelmingly or ubiquitously positive. Our review is consistent with research, which has found limited support for whole-school antibullying programs (J. D. Smith, Schneider, Smith, & Ananiadou, 2004). In accordance with the IOM (1994) framework, J. D. Smith and colleagues argued that the most important component of effective bullying prevention and intervention is systematic monitoring (i.e., maintenance). Therefore, programs are not necessarily the vital component for change; the people (i.e., school personnel, parents, students) who are committed to maintaining a culture of change are the vital component for change. The extensive effort and commitment that the published studies described on the part of participants is daunting and serves to stress the importance of careful evaluation of program elements and potential benefits/problems prior to engaging in the intervention. It is hoped the program summaries described in this chapter will provide an entry point for school practitioners considering similar efforts and provide a brief roadmap to the range of programs available.

Making sense of the conceptual support and causal models for some of the handful of available interventions with published empirical support is no easy task. In general, the published findings and reports do not explicitly cite clearly articulated and well-developed theoretical frameworks or create distinct causal models based on such frameworks (some of the programs reviewed here were notable exceptions in this regard)—the underlying causal models are critical for school personnel in creating evaluation components, diagnosing intervention problems, and revising less effective program elements as interventions progress. The bullying intervention field, in general, needs to improve this aspect of current and proposed intervention programs.

What is striking from this review is that many of the existing bullying prevention and intervention programs do not incorporate interventions based on theory. In fact, none of the published prevention and intervention programs address issues of homophily, dominance, and attractiveness theory in their programming. Thus, while theory guides us to specific interventions (e.g., have students in middle school stay in their same peer groups instead of changing groupings each year and thus setting up the need to establish dominance each year), existing programs are guided by broad social learning and social ecological theories. While these broad social theories are important for understanding the complexity of the bullying dynamic, they do not provide specific intervention strategies that can be easily implemented into myriad school settings.

While there is clearly some room for improvement, higher quality bullying interventions need to present a more developed and carefully crafted theoretical base. Such programs will also use carefully designed and selected pre/post measures to identify the specific problems present in a given context and to evaluate the effectiveness of the intervention in improving those problems. Using measures that accurately assess levels of the precise behaviors or attitudes targeted by the intervention, both before and after implementation, appears critical to understanding the program benefits, to program maintenance, and especially, to detecting any potential harmful effects.

Recommendations for Research and Practice

Effective bullying prevention and intervention must be data based. School personnel can follow the rubric for data-based decision making set forth in the book, *Bullying in American Schools: A Social-Ecological Perspective on Prevention and Intervention* (Espelage & Swearer, 2004). Individual schools can conduct whole-school surveys and/or questionnaires in order to assess the complexity of bullying that may occur in a particular school. These data can be used to guide prevention and intervention efforts. It is clear from this review and from the IOM framework, that maintenance of prevention and treatment efforts is vital. Bullying interventions are only helpful if they can be sustained. In fact, none of the programs reviewed in this chapter has a systematic plan for maintenance of a bully-free environment. There is a desperate need for rigorous testing of whole-school antibullying interventions (J. D. Smith et al., 2004), and there is a desperate need to identify inexpensive and realistic strategies for combating bullying that can be maintained over time. When school personnel partner with university researchers, we can collectively combat bullying in our nation's schools.

XLI
SCHOOL VIOLENCE

ANNE GREGORY
Curry School of Education, University of Virginia
ELISE CAPPELLA
New York University

Introduction

In the past 10 years, many communities were shaken by well-publicized shootings that resulted in multiple student deaths. Discussions about the problem of school violence increased. Fears of students as "super predators" were on the rise. While the events were certainly tragic, heightened concerns have not been grounded in the reality of declining violent crime in school settings over the past decade (National Center for Education Statistics [NCES], 2004). The chances of serious violent crime occurring in school are statistically quite low. During the school year 1999–2000, 16 of the 2,124 homicide victims who were school-aged children occurred in the school setting (NCES).

While violent crime may be rare, low-level aggression in schools is not uncommon. Thus, this chapter addresses prevalent behavior, to which many school staff are faced with on a daily basis. We define *aggression* as an intent or action to harm through verbal or physical force. A broad definition of aggression allows for a consideration of how delinquency in adolescents and young adults unfolds. For a group of serious offenders, aggressive actions begin early in life, gain momentum across the school years, and take on multiple and increasingly serious forms (Loeber, Burke, Lahey, Winters, & Zera, 2000). A preventive approach is called for in light of the escalation of aggressive behaviors across the school years.

Violence and Aggression in Schools

Rates of violence vary by the characteristics of the school. Violent crimes, including those against teachers, are more likely to happen in high schools than elementary or middle schools (NCES, 2004). Overall, urban schools have higher rates of violence than suburban and rural communities (NCES). Teachers in urban schools are more likely to be victims than those teaching in rural or suburban schools (NCES). Negative gang activities are particularly common in city schools, such that, in 1999, one third of city schools reported this as a problem (NCES, 1999). While urban schools have a particular confluence of poverty and violence, some evidence is suggestive that rural schools also have contextually specific patterns of violence. In 2003, students from rural areas, compared with urban and suburban areas, reported higher rates of bullying (NCES, 2004). A more in-depth study of three rural schools with students in grades three to eight also found high rates of bullying (Dulmus, Theriot, & Sowers, 2004). With greater residential stability and smaller populations in rural settings (Osgood & Chambers, 2003), perhaps rural students are more likely to attend years of schooling as a stable cohort leaving little room for reputations as victims or bullies to shift across the years.

Even with the variation in rates of violence across schools, there has been an overall downward trend in violence. A recent report issued by the U.S. Department of Education declared that school-based violent crimes against adolescents from 1992 to 2002 dropped by half (NCES, 2004). By 2003, 13% of high school students reported having been in a fight on school grounds—down from 16% in 2003. Similarly, students' reports of carrying weapons to school within the past month dropped from 12% to 6%.

Serious violent crime might be an infrequent occurrence, but low-level aggression appears to be more prevalent. The 1999 national school survey on crime and safety found that almost 30% of schools reported frequent bullying and almost 20% of schools reported frequent student acts of disrespect for teachers (NCES, 1999). In 2000, 3 million suspensions and 97,000 expulsions were reported. In some states, such as

Delaware and South Carolina, between 14% and 19% of the male students had been suspended (NCES, 2000). A study of 1992–1993 data from a random sample of disciplined 6th through 12th graders in 67 Florida school districts found that 47% of in- and out-of-school suspensions, corporal punishment, and expulsions were given for disruptive behavior in class, defiance of authority, or disrespectful behavior. The next largest offense, fighting, accounted for 9.5% of the disciplinary consequences (Florida Department of Education [DOE], 1995). The frequency of suspensions and expulsions and the reasons for such sanctions suggest that schools and counselors are faced with a serious problem of aggressive behavior.

Current Developments

"Get tough approach." Sociopolitical and historical developments affect how school violence and aggression is conceptualized and addressed. School counselors may have to navigate the tensions between a punishment orientation and a support orientation toward aggressive behavior. In response to increased public fear of school violence, many schools have taken an increasingly punitive, "get tough" approach. In the 1990s, zero tolerance policies were implemented across the states with a federal mandate passed in 1994, which called for a minimum 1-year expulsion for bringing a weapon to school (Gun-Free Schools Act). Critics of such policies argue that a mandate for expulsions does not take into account extenuating or contextual circumstances, which results in superfluous and overly punitive sanctions. The Harvard Civil Rights Project (2000) compiled case examples of children suspended or expelled for carrying sparklers, a Boy Scout pocketknife, a toenail clipper, and a toy ax for Halloween. They argued that punitive approaches to discipline may differentially affect African American and Latino students, who are overrepresented in suspensions and expulsions. In 1999, a survey showed that in grades 7 to 12, 20% of Hispanic students, 35% of African American students, and 15% of White students had ever been suspended or expelled (NCES, 2003). In light of the increasing numbers of students, particularly African American students, being suspended or expelled and with heightened fears of school violence, educational researchers (e.g., Devine, 1996) have documented the prison-like school environments that rely on video surveillance, metal detectors, and harsh sanctions.

Recognition of the complex needs of students provides a counterweight to the popularity of increased surveillance and harsh sanctions to reduce school violence. Some states and school districts are acknowledging the importance of addressing social and emotional development in school (Shriver & Weissberg, 2005), with states in every region across the United States mandating the teaching of social and emotional development alongside academic learning (National Association of State Boards of Education, 2005). In the mid-1990s, federal school safety funds spawned preventive interventions. Antibullying programs (e.g., Olweus, 1999), conflict mediation interventions (Johnson & Johnson, 1996), and on-campus suspension programs have become widespread. Concerns about the punitive approach of zero tolerance policies have generated new programs, such as a systematic school-based threat assessment to lower overreaction to a *perception* of student threat (Cornell et al., 2004). This may be helpful in addressing the problem of criminalizing youth, particularly youth of color.

Research-based interventions. Increasingly, school counselors may be asked to show the results of their interventions with evidence of decreased aggressive behavior and increased prosocial behavior. At the same time, counselors may be faced with the pressure to continue programs that are familiar to school staff, despite a lack of rigorous evidence that suggests they are helping. Currently, there is a federal push toward the use of evidence-based practice in schools, as seen in the establishment of the Institute for Education Sciences whose mission is to understand the effectiveness of education programs and improve academic achievement and access to educational opportunities for students. Efficacy and effectiveness research that utilizes experimental designs—randomly assigning schools, classrooms, or students to interventions—is prioritized in funding.

Faced with the pressure to show results, counselors may be called upon to ask critical questions of the research on interventions. This chapter aims to provide counselors with a knowledge base from which to raise such questions. It begins with an outline of the current research on the predictors of child and adolescent aggression. A theoretical understanding of how environmental factors interact with individual student characteristics to predict aggressive behavior will help counselors target risk factors specific to developmental stage and identify the reasons the intervention may help reduce aggressive behavior. With its focus on the prevention of serious school violence, the chapter then describes a range of research-based interventions. Several of the interventions focus on supporting students already identified as aggressive; others involve supporting individuals in the students' lives, namely teachers, parents, and peers. Also described are multilevel programs that intervene systematically across a range of settings and with different types of participants. Finally, the chapter provides counselors with concrete strategies to consider when selecting and developing interventions.

Aggressive Behavior in School

Individual Student Characteristics

Individual students differ in many ways—in their approach to social situations, in their struggles or successes with academic schoolwork, and in the ways their bodies are made up. These differences have been hypothesized to contribute to the behaviors students are likely to use in school. Researchers have isolated each of these individual characteristics to examine their relative contribution to the development and use of overt aggression in school settings. However, none of these factors operates separately from one another or outside the contexts of family, school, and community. We will outline the theory and evidence for the biological, cognitive, and academic differences associated with overt aggression, while keeping in mind the complex and interactive pathways through which aggression develops in students in school.

Biological factors. Possible biological contributors to overt aggression include genetic inheritance, temperament differences, neurotransmitter effects, and hormonal influences. This literature has been reviewed thoroughly elsewhere and will be summarized only briefly here (see Berman, Kavoussi, & Coccaro, 1997; Brain & Susman, 1997; Coie & Dodge, 1998).

Behavior-geneticists have postulated that a *tendency* toward aggressive behavior can be inherited, but aggressive behavior itself cannot (see Coie & Dodge, 1998). For example, biological genotypes passed down from parent to child may affect physiological processes, which influence a child's behavioral or cognitive style, which then interact with environmental factors to lead to behaviors. Twin and adoption studies from around the world support the theory. Genetic factors influence individual characteristics such as impulsivity and reactivity, and these may lead to a *disposition* toward externalizing behavior (e.g., Matheny, 1989), but there appears to be no relationship between genes and *actual* physical aggression or violence (Mednick, Gabrielli, & Hutchings, 1984; Raine, 1993).

Children's temperament has been hypothesized to relate to future behavior, in part through the stability of personality characteristics and in part through an interaction with environmental influences such as relationships with parents and peers. Early demonstrations of emotional regulation—for example, ability to inhibit inappropriate behaviors, cope with arousal, and organize for goal-oriented behavior when experiencing strong emotions—have been thought critical to children's later use of aggression (Dishion & Patterson, 1997). Research has demonstrated qualified support for these hypotheses: temperamental characteristics in preschool are stable over time (Bates, Bayles, Bennett, Ridge, & Brown, 1991), but a "difficult" temperament does not necessarily predict future delinquency (Caspi, Henry, McGee, Moffitt, & Silva, 1995; Earls & Jung, 1987). In addition, associations between early temperament and later aggression tend to be weak, confounded by use of maternal reports, and linked with parent–child attachment (Bates, Maslin, & Frankel, 1985) and the home environment (Earls & Jung). That said, *connections* between disposition and cognition (discussed next) may help to explain *some* children's aggressive responses to environmental stimuli (Dodge, 1991).

The framework for understanding the role of neurotransmitters in aggressive behavior is Gray's (1987) theory of brain function; in particular, his description of the behavioral facilitation and behavioral inhibition systems within the brain that launch or halt interactions with the environment. Although engagement or inhibition of activity is related to multiple neurotransmitters, concentration of *serotonin* metabolites in the cerebrospinal fluid is critical, such that low concentrations may lead to an increase in stress reactivity (Berman et al., 1997; Spoont, 1992). Studies of serotonin in children indicate that lower concentrations are, in fact, related to conduct disorder in adolescents (Pliszka, Rogeness, Renner, Sherman, & Broussard, 1988) and disruptive behavior disorders among children (Kruesi et al., 1992). However, investigators and theorists postulate a reciprocal transaction, such that the levels of neurotransmitters not only are genetically determined, but also respond to early environmental influences and socialization (see Rogeness, Javors, & Pliszka, 1992).

Finally, testosterone has been suggested to play an organizing or activating role in physically aggressive behavior, the former occurring during the perinatal period and the latter occurring during puberty (Brain & Susman, 1997). Study results have been conflicting (Inoff-Germain et al., 1988; Olweus, Mattsson, Schalling, & Low, 1988; Susman et al., 1987), and Archer (1994) attempted to explain the differences in theory and research in a dynamic model that posits early gender differences due to hormonally driven activity levels that lead boys and girls toward different play subcultures with a different need for physical aggression. These subcultures then interact with broader societal influences, individual temperaments, and baseline levels of testosterone. Later in adolescence, when testosterone levels are rising, a child's established patterns of aggression interact with hormones to produce more or less aggression, which fuels future testosterone if the aggression induces feelings of dominance and success. Although not empirically tested, this model is a compelling explanation of the role of testosterone as an *interacting* agent across time influencing children's aggression.

Social cognition. Beyond biological factors, individuals bring particular cognitive styles to social interactions (Dishion & Patterson, 1997). One of the most studied cognitive theories, social information processing, suggests that a social situation triggers a succession of cognitive and emotional operations that first represent, then interpret, the situation (Dodge & Schwartz, 1997). When these operations are effective and accurate, the social behavior is adaptive; when the operations are biased, the behavior is often maladaptive. A set of conscious and unconscious steps are hypothesized to occur repeatedly; however, children may develop patterns that simplify the steps and create relatively stable behavioral responses to situations over time (Huesmann, 1988; Schneider, 1991).

Researchers have used correlational studies with hypothetical social scenarios to examine the links between different aspects of the social cognitive processing model and children's aggressive behavior. For the most part, these studies have verified the connection between social information processing skills—for example, attending to and recalling social cues, requesting additional information, interpreting others' intentions, generating responses to the situation—and aggressive behavior (see Dodge & Frame, 1982; Dodge, Pettit, McClaskey, & Brown, 1986; Guerra & Slaby, 1989; Quiggle, Garber, Panak, & Dodge, 1992; Slaby & Guerra, 1988; Spivak & Shure, 1980). In addition, several studies indicate that aggressive children evaluate aggressive actions in a more positive light than do their nonaggressive peers (Guerra & Slaby), value the results of aggression more highly (Boldizar, Perry, & Perry, 1989), and have positive efficacy beliefs for the use of aggression (Crick & Dodge, 1989). However, the deficits in social information processing have been shown to differ based on the child's use of a particular subtype of aggression, in particular, reactive aggression (retaliation based in anger and frustration) and proactive aggression (unprovoked and goal-directed behavior; Dodge & Coie, 1987). Use of reactive aggression has been linked with hostile attributional biases, whereas use of proactive aggression is related to positive evaluations of aggressive behaviors and instrumental goals for social situations (Crick & Dodge, 1996).

Academic skills. An extensive body of research demonstrates a strong relationship between externalizing behavior problems and academic underachievement, with comorbidity up to 50% when including a broad set of externalizing syndromes and indications of school failure (Barkley, Fischer, Edelbrock, & Smallish, 1990; Hinshaw, 1992). A recent meta-analysis demonstrated that students with emotional behavior disorders (EBD) performed significantly worse across settings and subject areas than their nondiagnosed peers (R. Reid, Gonzalez, Nordness, Trout, & Epstein, 2004). A meta-analysis of the link between underachievement and delinquency revealed that academic difficulties were related to the onset, level, frequency, and persistence of delinquency in both males and females (Maguin & Loeber, 1996). Early in schooling, the link can be explained primarily by inattention and hyperactivity (Frick et al., 1991); in adolescence, the association grows increasingly robust (Hinshaw).

Paths between underachievement and delinquency have been hypothesized to be unidirectional (problems in one domain cause problems in the other; e.g., Hirschi, 1969; Rutter & Giller, 1983) or cyclical (bidirectional influences between domains). Deficits in academic skills may lead to aggressive behavior through task frustration, lack of motivation, low academic self-concept, and school disengagement (see Arnold et al., 1999). For example, continued academic problems may produce a negative association with schooling, thus increasing the likelihood of hostility, disobedience, and aggression in school (McEvoy & Welker, 2000). High levels of externalizing, on the other hand, have been thought to lead to academic problems through reduced time on task related to social skills deficits, inattention, or noncompliance (Arnold et al., 1999; McEvoy & Welker). Acting out in the classroom may help an underperforming student avoid academic tasks or may distract the teacher from the student's academic problems (Carr, Taylor, & Robinson, 1991).

Despite methodological problems, studies have provided some evidence of predictive, if not causal, pathways between academic skills and aggression. A subset of children with reading failure but no behavior problems in childhood has been shown to grow into adolescents with antisocial tendencies (Maughan, Gray, & Rutter, 1985). A delay in the onset of reading relates to later externalizing problems (e.g., McGee & Share, 1988), and aggression in middle childhood predicts low academic achievement in adulthood after controlling for early intelligence test scores (Huesmann & Eron, 1986). Finally, through such mechanisms as speech delay, familial adversity, and neurodevelopmental immaturity (e.g., Howlin & Rutter, 1987; Richman, Stevenson, & Graham, 1982; Tallal, Dukette, & Curtiss, 1989), aggression and learning are linked even before a child begins school (see Hinshaw, 1992). This provides additional support that the connection between aggression and achievement is complex and multifaceted, beginning early in development and interacting across contexts and domains to reinforce the relationship.

Final issues. The research summarized briefly provides theory and evidence of individual student factors within the biological, social–cognitive, and academic domains related to the use of aggression in schools. This extensive body of research has limitations. First, male students tend to be

overrepresented and female students underrepresented in the study samples. This leads to a lack of complete knowledge about possible gender differences in the development of aggression, particularly as related to hormonal influences (e.g., Inoff-Germain et al., 1988; Susman et al., 1987) and links to achievement. A second and related limitation is that studies define aggression as overt or direct, rather than covert or indirect. An emerging area of interest among researchers and school personnel alike is the development and use of subtle forms of aggression in schools (see Crick, 1996; Underwood, 2003), but the pathways toward the use of social or relational aggression are less understood (see Kaukianinen et al., 1999; Xie, Swift, Cairns, & Cairns, 2002). Finally, although researchers have isolated these areas to study the development of aggression, most models are dynamic and comprehensive, linking biological, social–cognitive, and academic domains, as well as the multiple social contexts in which students live, work, and play.

Characteristics of the Social Context

Children traverse multiple social contexts as they develop across their years of schooling. The primacy of the home context shifts as they enter schooling and interact with peers. They encounter new adults in classrooms and are asked to abide by the structures of the daily school routines and rules. They draw on multiple communities outside of school and the home while being exposed to mass media and entertainment. In interaction with a child's attitudes and attributes, these social contexts provide key experiences that shape development, including acerbating or escalating aggressive or violent behavior. A review of the literature suggests that family, peers, neighborhoods, mass media, schools, and classrooms should be considered when examining the ecology of the developing child.

Family. Children can transfer negative behaviors learned with family members into the school setting (e.g., Earls, 1981). Family research has identified two areas of the home context that have been linked to children's and adolescents' aggressive and violent behavior: (a) parent–child interactions and (b) parenting practices. Focused on the patterned exchanges between parents and their children, Patterson and his colleagues have investigated a social interactional theory of the development of aggressive behavior (J. B. Reid, Patterson, & Snyder, 2002). Drawing on principles of operant conditioning, they have documented coercive cycles between parents and young children whereby a child's whining or tantrums are rewarded when a parent gives in to the child's request. These interlocking reinforcement patterns repeat themselves daily and children learn that aggressive behavior ushers in positive results. Investigators have also studied how children learn from adult modeling of aggression (Bandura, 1973), especially related to parents' discipline practices. From a social learning theory perspective, if an adult expresses anger by physically punishing the child, then the child may learn to do the same. Longitudinal studies have linked physical punishment to later aggression and delinquency (Eron, Huesmann, & Zelli, 1991; Farrington & Hawkins, 1991). Supervision during adolescence has also been studied as a parenting practice linked to aggression. Providing structure and adult guidance for adolescents has been posited as developmentally appropriate, even during a stage when needs for autonomy increase (Connell, 1990). Several longitudinal studies have shown that a lack of parent supervision is one of the strongest predictors of adolescent conduct disorder and delinquency (e.g., Hawkins, Herrenkohl, & Farrington, 1998).

Increasingly, scholars recognize that parenting practices should be considered within cultural context (Baumrind, 1991). Generalizations about the detrimental effects of particular parenting practices can be hard to make when for some families in certain neighborhood contexts such practices may be protective. For instance, Lansford, Deater-Deckard, Dodge, Bates, and Pettit (2004) showed that for African Americans, unlike for White adolescents, physical discipline such as spanking was linked to lower externalizing problems. A similar cultural specificity may be considered when examining the role of parental supervision and adolescent aggression. While some evidence shows that authoritative parenting may be linked to positive outcomes for adolescents from diverse groups (Gregory & Weinstein, 2004), culturally specific findings (Gonzales, Cauce, & Friedman, 1996; Steinberg, Lamborn, & Darling, 1994) present a more complex picture. Strict monitoring was adaptive for adolescents living in high-crime neighborhoods (Eamon, 2001; Gonzales et al., 1996), suggestive of the benefits of an authoritarian parenting style.

Peers. As early as 1939, Sutherland theorized that peers make up a crucial social context in which aggressive and violent norms are transmitted. Since then, empirical research has firmly established the reciprocal relationship between friendship networks and behavior (e.g., Dishion, French, & Patterson, 1995). Negative peer experiences (both peer rejection and "deviant" peer affiliation) have been cited as "on-ramps" to adolescent aggression (Laird, Jordan, Dodge, Pettit, & Bates, 2001). Aggressive children are more likely to be rejected by their classmates, which then increases the risk for later antisocial behavior (Asher & Coie, 1990). In fact, research has shown that the link between peer rejection and antisocial behavior is mediated by affiliation among aggressive peers (Dishion, Patterson, Stoolmiller, & Skinner, 1991). In the early years of schooling,

a pattern of negative interactions with peers can become relatively stable across the school year for aggressive children (Snyder, 2002). These children are reinforced for their behavior, but often rejected by other peers. Seeking social niches that will hold them in high regard, they develop relationships with other aggressive children (Thornberry & Krohn, 1997). Longitudinal studies have shown that affiliation with an aggressive peer group is a powerful predictor of the persistence and progression of antisocial behavior (Moffit & Caspi, 2001; Patterson, Dishion, & Yoerger, 2000).

Within peer networks, friends may support and encourage each other's aggressive behavior through positive reinforcement and modeling. In observational studies of adolescents, researchers have shown that peers reinforce each other's aggressive talk and behavior through both verbal and nonverbal behavior (Buehler, Patterson, & Furniss, 1966; Dishion, Andrews, & Crosby, 1995; Dishion, Spracklen, Andrews, & Patterson, 1996). Moreover, displays of toughness and power can help an adolescent gain status and, for males, reinforce a type of masculine identity (Fagan & Wilkson, 1998). The processes of impression management, peer reinforced aggressive behavior, and expected gender roles need further examination. That said, research has firmly established that it is important to consider a teenager's friendship group to understand heightened aggression, especially during the adolescent years.

Neighborhood and media influences. A review of studies showed that differences in neighborhoods have a small to moderate effect on delinquency and violence (Leventhal & Brooks-Gunn, 2000). The mechanisms through which neighborhoods affect children's development include institutional resources, relationships, and the norms and collective efficacy in neighborhoods (Jencks & Mayer, 1990; Leventhal & Brooks-Gunn). For instance, access to high-quality childcare, with low adult-to-child ratios, is limited in poor neighborhoods (Fuller, Coonerty, Kipnis, & Choong, 1997); this resource is linked to positive behavioral outcomes (e.g., Benasich, Brooks-Gunn, & Clewell, 1992). Protective relationships may also be lacking or compromised in low-income communities. Economic hardship has been thought to increase parents' social isolation, stress, and depression, which then compromises their ability to provide monitoring (Conger et al., 2002). Lower monitoring predicts higher rates of delinquency (Hawkins, Herrenkohl, & Farrington, 1998). The benefits of watchful community members may also be compromised in low-income neighborhoods with high residential turnover. These neighborhoods have been shown to have weak norms to control aggressive behavior and low collective efficacy to change the neighborhood (Sampson, Morenoff, & Earls, 1999). Cut out from mainstream economic opportunities, key pathways out of poverty may be lost, which leaves generations trapped in poverty and exposed to violent neighborhoods (Hill, Fernando, Chen, & LaFrombois, 1994). Such exposure has been prospectively linked to greater aggressive behavior (Gorman-Smith & Tolan, 1998).

Increasing evidence has established a link between exposure to media violence and aggressive behavior (Anderson & Bushman, 2001). The link is robust and replicable, although not statistically large (Huesmann, Moise, & Podoloski, 1997). Experimental conditions in the lab have shown that exposure to violent media increases the likelihood of physical assault (see Anderson, Berkowitz, & Donnerstein, 2003, for a review). Longitudinal studies support the laboratory findings. For instance, in a study spanning over 25 years, Huesmann (1988) found that criminal convictions at age 30 were linked with preference for violent television in the third grade. Substantial evidence supports theories of observational learning of behaviors and cognitions to help explain why media exposure predicts aggression. Children replicate the behavior of admired television characters (Huesmann & Eron, 1986) who receive rewards for their acts of violence (Bandura, 1973). Via the media, children learn cognitive scripts for aggressive behavior and develop beliefs about the acceptability of aggression as a means to a goal (Huesmann et al., 1997).

Schools. Schools have been shown to differ in their rates of aggression and violence even when taking into account the characteristics of the enrolled students (Rutter, Maughan, Mortiore, & Ouston, 1979). Such differences have prompted inquiry into school policies, procedures, and structures that distinguish low from high aggressive schools. Three underlying theoretical approaches differentiate research in this area. The first approach implies that there is a developmental mismatch between students and the way schooling is organized such that the school either lacks appropriate monitoring or lacks appropriate autonomy. Said differently, schools are seen as under or overcontrolling. The second approach posits that students are not given the opportunity to bond with school whereby they do not become personally invested in the rules and in the community. The third approach suggests that schools' organization of students results in reinforcing maladaptive behavior. Research with these approaches has been conducted primarily at the elementary school level, yet evidence is suggestive that they may be helpful in understanding middle and high school effects on aggression.

Mismatched with young children's developmental needs, some schools may lack consistent, schoolwide expectations for behavior (Horner, Sugai, Lewis-Palmer, & Todd, 2001) or adequate supervision throughout the school grounds. Specific settings in the school may be particularly conducive to aggressive behavior. Using naturalistic observations of elementary students, Craig, Pepler, and Atlas (2000)

found that, compared with behavior in classroom settings, children exhibited more aggression on the playground, where very little teacher intervention occurred. J. B. Reid and colleagues (1999) also showed that less supervision during recess was linked with higher levels of aggression. Additional settings such as hallways and lunchrooms may also need to be examined for their lack of appropriate supervision. Behavioral regulation, while underemployed in certain settings in the elementary school grades, may be implemented in a counterproductive manner in later grades without consideration for adolescents' increasing need for autonomy. Hyman and Perone (1998) argued that police presence, metal detectors, and locker searchers are displays of control and disrespect. Zero-tolerance and punitive suspension policies may also contribute to a culture of threat and control (Ayers, Dohrn, & Ayers, 2001). In repressive school environments, students may respond with moral indignation and active resistance (Giroux, 1983). Correlational research has shown that students' perceptions of feeling respected and perceiving clear and fair rules are linked to lower rates of discipline (Gottfredson, Gottfredson, & Hybl, 1993; Hollingsworth, Lufler, & Clune, 1984). Additional research on students' responses to school cultures of threat and surveillance is needed.

Schools may vary in the degree to which they offer the conditions that promote school bonding, which has been theorized as a factor that can lower aggression and violence. Combining social control theory (Hirschi, 1969) and developmental theory, Hawkins, Smith, and Catalano, (2004) have conceptualized school bonding as a commitment to doing well in school and an attachment to those at school, characterized by close emotional relationships. They posit that a strong social bond asserts an informal control on a student's behavior. Evidence to support their theory has accrued. Lowered school bonding has been linked to escalating aggression during the teen years (Hawkins, Guo, & Hill 2001). Relatedly, Battistich, Solomon, Watson, & Schaps (1997), in a longitudinal study across elementary grades, found that students' sense of community predicted lower delinquency.

School policies on tracking and ability grouping may also be linked to the problem of aggression. The drawbacks of homogenous grouping have been examined from the perspective of operant conditioning principles such that students who behave similarly reinforce each other's behavior and, by doing so, strengthen it. Some evidence is suggestive that classroom placement can have long-term effects on the escalation of aggression. Kellam, Ling, and Merisca (1998) found that first graders perceived as high in aggression had higher rates of aggression in sixth grade if they were placed in first-grade classrooms with high mean levels of aggression. They concluded that tracking aggressive children with similar children can have detrimental effects. Similarly, grouping lower achieving students together has been linked to increasing behavior difficulties over time (Werthamer-Larsson, Kellam, & Wheeler, 1991). In fact, some scholars have described the sorting of students as "structural violence." They argue that the monitoring of African American students as "behavior disordered" in special education serves to colonize and control this population of students, which leads to stigmatizing labels (Watts & Erevelles, 2004).

Classrooms. Classrooms in the early grades and the later grades have been shown to differ in levels of discipline problems (Baerveldt, 1992; Gregory, Nygreen, & Moran, 2006). Inquiry into what differentiates classrooms with higher levels of aggression and disruptive behavior can be grouped into three approaches. The first approach emphasizes the teachers' abilities to manage the classroom as a whole. Of importance are teachers' skills in engaging the students in academic tasks without being sidetracked by disruption. The second approach emphasizes the quality of teachers' relationships and interactions with individual students. The third approach focuses on teachers' attitudes and expectations that are brought into the classroom. While most of this research has been conducted at the elementary school level in single classrooms, some middle- and high-school-level research has sought to understand divergent behavior across classrooms (e.g., Gregory & Weinstein, in press).

The findings of Jacob Kounin (1970) are relevant today in understanding the importance of group management for well-run classrooms. Kounin found that more important than their specific discipline techniques, teachers with less aggression in their rooms were skilled at keeping the whole classroom on task and, thus, prevented escalating problems with aggression. Using systematic coding of videotaped elementary schools classrooms, Kounin found five skills that were linked with lower disruptions. "Withitness" is a teacher's preemptive actions and heightened awareness of behavior in the classroom. With quick and subtle interventions, a skilled teacher intervenes early to keep students engaged in the academic tasks. "Overlapping" is a teacher's ability to multitask with a focus on keeping the academic lesson going. He or she is able to address off-task behavior without derailing the lesson. "Momentum" helps transitions occur quickly with little time for losing students' motivation. "Smoothness" keeps the lessons focused with minimal deviations from the task at hand. "Group alerting" uses skills to keep each student engaged without letting some drift off. Overall, these teachers are able to anticipate problems with a focus on the antecedents of misbehavior (Emmer, Evertson, & Worsham, 2003; Evertson, Emmer, & Worhsam, 2003).

Indicators of well-run classrooms include how teachers interact with individual students. Reviews of research on classroom discipline have shown consistently that frequency of positive reinforcement is linked with orderly classrooms and low levels of misbehavior (see Doyle, 1985). The importance of positive feedback supports theories of operant conditioning, whereby behavior is strengthened when it is reinforced. The quality of interactions has also been examined from a relational standpoint. Close teacher relationships have been shown to serve as protective factors for young children at risk of negative discipline trajectories (Pianta, 1999). Evidence suggests that students' experience of teachers as nurturing with high academic expectations are linked to positive social and behavioral outcomes for middle school (Wentzel, 2002) and high school students (Gregory, 2004). Teachers, like parents, may help establish positive emotional climates with children (Davis, 2002). Within this climate, teachers may develop trust with students that enables them to effectively prevent or de-escalate aggressive behavior (Gregory). Or, teachers may develop effective regulatory processes with their students (via the relationship) to help students identify and control their emotions (Pianta & Weinstein, in press).

Teacher attitudes and expectations may exacerbate or prevent escalating aggression in the classroom. Research in this area asserts that teachers enter classrooms with preconceived notions of students, which affect their teaching practices. Though conducted mostly at the elementary school grade levels, research on teacher perceptions suggests that, on average, teachers are more likely to hold negative judgments of students of color than of White students (Weinstein, 2002). For instance, compared with teachers of color, White kindergarten teachers were more likely to report having conflict with their students of color (Saft & Pianta, 2001) and report overall higher rates of student difficulty in following directions (Rimm-Kaufman, Pianta, & Cox, 2000). From her ethnographic study of an elementary school, Ferguson (2000) argued that White teachers draw on stereotypes and their own fears of difference when they perceive "defiance" in African American students. In their large study of urban middle schools in the Midwest, Skiba and colleagues (2002) identified reasons for suspension given to African American students as more subjective compared with reasons for suspensions given to White students. In a path analysis explaining the disproportionate sanctioning of Black students, McCarthy and Hoge (1987) found that, despite Black and White students' similar self-reports of misconduct, teachers' evaluation of the students' demeanor explained a significant amount of the association between race and sanctions received. Additional research is needed to examine students' behavioral response to differential treatment.

Final issues. The social contextual effects on aggression often have small to moderate effect sizes, with meaningful implications for the escalation of aggressive behavior across schooling. That said, limitations of the empirical understanding of social contextual effects need to be highlighted. While it is helpful to pinpoint a given setting's particular effects on aggression, the reality of interacting settings is far more complex. Ecologically grounded research that accounts for the interacting influences encountered in a given day and across developmental stages is needed. The field is only beginning to address the generalizability and the cultural specificity of particular processes. Differences related to gender, social class, race and ethnicity, and region may influence how and why some social forces have more or less impact on some children's behavior.

Continuous and Reciprocal Interactions Between Individuals and Contexts

Individual attitudes and attributes interact with social contextual influences in a dynamic and reinforcing fashion (Rutter & Sroufe, 2000). Thus, across a child's life, genetic, neural, behavioral, and environmental systems likely interplay in a bidirectional manner (Gottlieb & Halpern, 2002). A life-course developmental model of aggressive behavior points to critical windows when particular risk factors play a greater or lesser role (J. B. Reid & Eddy, 1997). Longitudinal research has helped to identify when such risk factors set in motion negative developmental trajectories within particular subgroups of children. Confirmed by other studies, Patterson (1995) and Moffitt and Caspi (2001) delineated between early childhood onset of aggression, which is more likely to be life-course persistent, and adolescent onset of aggression, which is more likely to desist in early adulthood. These early-onset children often exhibit aggressive behavior outside the normative developmental levels before they start formal schooling. An interplay between individual factors (e.g., attentional problems, low verbal IQ, or irritable temperament) and family factors (e.g., disrupted inconsistent parenting, parents with a history of antisocial behavior, or coercive parenting) has been shown to be a strong predictor of such early onset. Thus, in these early years between infancy and 5 years of age, family and individual risks factors are particularly salient (J. B. Reid & Eddy).

When the "early-onset" children enter formal schooling, another set of risk factors exacerbate the aggressive behavior. School and peer factors such as a lack of positive teacher attention, academic underachievement, and rejection by peers, contribute to the "snowballing" of the problem. In high school, these children with histories of aggressive behavior are matched by another subgroup of later onset youth (Moffit and Caspi, 2001). For both

groups of teens, a lack of adequate monitoring by parents accompanied by affiliation with high-risk peers exacerbates the aggressive behavior. Equipped with a developmental perspective that considers multiple pathways and risk factors that co-occur between individuals and their social contexts, school counselors can better understand how aggressive behaviors can become more wide-ranging in scope and seriousness across children's years in schooling.

Counseling Practice to Reduce School Violence

Current Practice in Schools

Recent efforts abound to study the effectiveness of school-based interventions to prevent violence and aggression (see Durlak & Wells, 1997; Henrich, Brown, & Aber, 1999; Johnson & Johnson, 1996; Leff, Power, Manz, Costigan, & Nabors, 2001; Wilson, Lipsey, & Derzon, 2003). Based in theory and research, most programs with evidence of effectiveness have been designed and evaluated by university researchers. These demonstration programs focus on building competence and/or addressing deficits within the individual student (e.g., cognitive processing skills, academic achievement), supporting and/or changing one or more social contexts (e.g., playground, classroom), or both. Prevention programs have been found to have the largest effects on the highest risk populations (Wilson, Gottfredson, & Najaka, 2001). Unlike demonstration programs, "routine practice programs"—those that currently exist in schools—generally have not been studied, have been shown to be minimally effective, or are evidence-based programs being inadequately implemented (see Wilson et al., 2003). In the following sections, we will outline some common routine practice programs and several effective demonstration programs to prevent and/or reduce aggression and violence in schools.

Routine practice programs. One common practice to reduce school violence involves the removal of disruptive students from the situation (e.g., detention or suspension) either alone or in combination with a parent–teacher conference (Gottfredson et al., 1993; Tolan & Guerra, 1994). Although research has demonstrated the importance of consistent consequences for violation of clear school rules (e.g., Colvin, Sugai, Good, & Lee, 1997), the long-term effectiveness of punitive disciplinary measures in reducing or preventing violence is not evident (see Skiba, Peterson, & Williams, 1997; Mayer, 1995). Similarly, when parent–teacher conferences are oriented toward problem solving and establishing consistent policies and communication across home and school, they may be helpful. However, when they occur only after negative events and emphasize punishment, their helpfulness in reducing the problem behavior is questionable.

A second widespread practice involves providing psychological testing and/or supportive counseling for individual students. Although an educational and psychological assessment may be a reasonable first step for the most disruptive students, it is not a realistic preventive or treatment solution given the tremendous resources needed to carry out this approach for all whose behavior and achievement may suggest it. In addition, supportive counseling (noncognitive behavioral therapy) has not been demonstrated to be effective in reducing aggression in the contexts in which disruptive children and youth act out (Wilson et al., 2001). Finally, even when school personnel try to implement evidence-based demonstration programs, for many reasons, the implementation of these interventions is often inadequate, thus reducing the likelihood of effectiveness. In a recent review, Gottfredson and colleagues (2004) found that only 57% of delinquency prevention activities in schools were implemented to a satisfactory level in terms of duration, intensity, and frequency of activities; content of programming; method of delivery; and participation among staff and students.

Demonstration programs. Many preventive and treatment programs designed and supported by a university-based research team have been the subject of rigorous examination documenting at least moderate effectiveness within particular school–community contexts when implemented with fidelity. The intervention programs are based in theory and research, and focus on the students (e.g., as individuals or groups), the social context (e.g., classroom, playground), or both (e.g., multilevel and whole school). A recent meta-analysis of school-based intervention effects on aggressive behavior indicates that well-implemented, intensive, teacher-administrated, behavioral/academic/social competence programs can have a sizeable impact on student aggression (Wilson et al., 2003). We will discuss several of these programs next. In addition, we will describe some well-studied multimodal programs that may have smaller effects on aggressive behavior (see Wilson et al., 2003) but may have an impact *across* domains of student development such as social competence and academic learning. Given the differences in program effectiveness when programs are supported by a research team versus implemented without support, recommendations will be provided to counselors interested in utilizing an evidence-based approach in their schools to maximize the possibility of a positive impact on student aggression and violence.

Indicated or Treatment Programs

Typically, counselors intervene with individual students who already have demonstrated aggressive behavior with the aim of preventing the unfolding of a full-scale disorder. A recent meta-analysis showed that school-based programs that aim to prevent the escalation of aggression are most effective with students who already have exhibited aggressive behavior (Wilson et al., 2003). School interventions may be individual, parent, or group focused; however, the configuration of interventions with identified students is under strict scrutiny. With cost effectiveness a priority, schools often place aggressive children in group interventions, where students with similar difficulties interact in weekly meetings. Recent research on the negative peer influences in groups has raised questions about the unintended iatrogenic effects of group-format interventions at the elementary and middle schools (Boxer, Guerra, Huesmann, & Morales, 2005) and the high school level (Cho, Hallfors, & Sanchez, 2005). At this point, additional research is needed to understand whether mixed student groups are more or less beneficial than homogenous groups and whether high-aggressive or low-aggressive peers undermine or enhance intervention goals (Dishion & Dodge, 2005). With caution in mind, a well-studied group-based intervention follows. Then, we will describe a school-based parenting intervention, followed by a well-established individually focused intervention.

Anger Coping Program. The Anger Coping Program was designed as an 18-session, small–group format intervention with aggressive children (Lochman, Barry, & Pardini, 2003). The program draws on a social–cognitive approach, which emphasizes that children's perceptions of conflicts, encoding of relevant details, and interpretation of others' intentions are linked with their behavioral response (Crick & Dodge, 1996). Using a curriculum, group leaders address the following topics: anger management, perspective taking, socials skills training, goal setting, coping with peer pressure, emotional identification, problem solving, and relaxation training (Lochman et al., 2003). Sessions vary with a range of interactive tasks such as practicing calming self-talk while being teased, role-playing conflicts from different perspectives, and videotaping the negative consequences of an aggressive action.

The Anger Coping Program has been administered primarily in middle schools for boys identified as exhibiting aggressive behavior. It has been run as a single intervention (e.g., Lochman, 1992) and in combination with a parenting intervention (e.g., Lochman & Wells, 2004). Chorpita and his colleagues (2002) concluded in their review of three relevant studies that the intervention has a modest effect size in reducing aggressive behavior. In one study, only those who received a booster intervention the next school year showed significant reductions in classroom, off-task behavior (Lochman, 1992). The most recent published evaluation showed more promising results. The program was aimed at fifth- and sixth-grade boys who had relatively high aggressive ratings by parents and teachers (Lochman & Wells). Small groups of 4 to 6 boys participated in 32 sessions across 2 school years. The year after the intervention was completed, teachers rated the boys as improved in behavioral problems, anger management, and problem solving. No moderating effects of race were found such that the intervention effects held for the sample of White and African American boys. While the Anger Coping Program is a promising intervention, as mentioned previously, care should be taken when grouping aggressive children and adolescents in sustained "pull-out" programs (Dishion & Dodge, 2005).

Functional behavioral assessment and intervention. The 1997 and 2004 reauthorizations of the Individuals with Disabilities Education Act require schools to address discipline problems with students in special education using functional behavioral assessment and intervention. Grounded in behaviorist and social learning theory, functional analysis and intervention is frequently conducted with students exhibiting aggressive or disruptive behavior (Quinn et al., 2001). Crone and Horner (2003) described the procedures in detail. A teacher and counselor gather data about environmental factors that precede and follow the behavior. Hypotheses about the predictors and function of the behavior are developed. For instance, students may engage in problematic behaviors to obtain or escape something in the classroom (Ervin et al., 2001). Once hypotheses are formed about what drives the behavior, interventions are then designed to make the behavior irrelevant, inefficient, and ineffective (Crone & Horner, 2003). Interventions can include teaching a child an appropriate replacement behavior to obtain the desired goals or eliminating the reinforcers that strengthen the negative behavior (Ervin et al., 2001).

The functional approach to changing individual behavior in the classroom seems to be ahead of the research supporting its widespread use. While examination of 100 studies using functional behavioral assessment and intervention with 278 students showed positive short-term gains, most of the studies have been conducted with preschool and elementary students with disabilities (Ervin et al., 2001). Research with older students and those without disabilities is scarce. Moreover, long-term follow up to ascertain if the gains are sustained is rare. In addition, this approach can be quite time intensive and requires anywhere from 1 week to 30 days (Quinn et al., 2001). Thus, whether it is a cost-effective use of teacher and counselor time in comparison with classroom-wide interventions

remains open to question. That said, a recent meta-analysis concluded that interventions based on learning principles and behavioral theory are most effective compared with other interventions such as mentoring or supportive counseling (Wilson et al., 2001). Thus, despite the fact the research on functional behavioral assessment and intervention is lagging, it is a promising approach that has become expected professional practice.

Parenting—The incredible years. For the past 20 years, Carolyn Webster-Stratton and her colleagues at the University of Washington Clinic have been developing interventions with young children to prevent the onset and escalation of conduct problems. After fine-tuning a parenting intervention, they developed child and teacher components (Webster-Stratton, 2005). Their program theory uses cognitive social learning principles with a focus on relationships. Using Patterson's interactional model (1982), they aimed to interrupt the coercive patterns that can become established between children and parents, which have been predictive of aggressive behavior. They also emphasized the importance of the emotional climate between parents and children with the goal of reducing harsh and inconsistent parenting and increasing warmth and positive interactions. Their programs relied heavily on videotaped parenting vignettes to model effective and ineffective parenting (see Webster-Stratton). The BASIC training program has 13 to 14 weekly 2-hour sessions and teaches parents of 2- to 7-year-olds how to positively engage, use praise and rewards effectively, set limits, and deal with noncompliance. The ADVANCE program aims to maintain treatment effects by lowering the detrimental effects of relationship distress and divorce, which were found to be predictors of treatment relapse. The program attempts to strengthen interpersonal skills in coping, communication, problem solving, social support, and self-care. They also offer four to six additional sessions that address how parents can promote their children's learning.

The BASIC parenting intervention has been studied extensively and summarized in more detail elsewhere (Webster-Stratton, 2005). The bulk of the research was with White middle-class families and children aged 2 to 6 years. However, they have extended their scope to include more diverse populations and children up to 10 years old. In brief, six randomized controlled trials have shown that the intervention improves parent–child interaction and reduces child conduct problems. The intervention has resulted in sustained gains for half to three quarters of the participants. A 3-year follow-up study showed that children with single parents or parents with relationship difficulties or negative life stress were less likely to sustain benefits. The intervention has also been successfully implemented with a low-income, Head Start population (M. J. Reid, Webster-Stratton, & Baydar, 2004). Children and their mothers with more difficulties benefited the most. The parent training has shown that behavioral improvements can generalize to the school setting. A recent study showed that the children of the parents in the intervention sustained improved classroom behavior across one school year, as rated by teachers (Webster-Stratton, Reid, & Hammond, 2004).

Universal or Single Context Programs

Beyond programs focused on students who already have demonstrated some aggressive behaviors, several setting-wide programs have evidence of effectiveness. Some of these are curricula with the primary goal of building skills and competencies within individual children, such as the Promoting Alternative THinking Strategies (PATHS) curriculum or classwide peer tutoring. These programs have the potential benefit of impacting both those students who may be at risk of developing aggressive tendencies, as well as those who already use aggression in school. Others are interventions whose primary goal is to alter the functioning of a setting, such as teacher consultation and playground restructuring. In this case, addressing environmental or structural characteristics related to the promotion of aggression may be especially critical, particularly for children in elementary school (e.g., J. B. Reid, Eddy, & Fetrow, 1999).

PATHS. The Promoting Alternative THinking Strategies program is a 60-lesson curriculum taught by the elementary school classroom teacher over one school year and integrated into the classroom curriculum with an emphasis on both changing the environment and educating the child (Greenberg, Kusche, & Mihalic, 1998). In particular, the program is designed to increase student self-control, emotion understanding, positive communication, prosocial behavior, and interpersonal problem solving. This theory-based program derives from the ABCD model of development (affective–behavioral–cognitive–dynamic) in which children's internal and external coping arises from their combined emotion awareness, cognitive understanding, and behavioral skills, with the affective component preceding the cognitive and behavioral functions (see Greenberg et al., 1998). Teaching methods for the 20- to 30-minute lessons include direct instruction, discussion, role plays, modeling, and reinforcement. Lessons focus on labeling and managing feelings, delaying gratification and controlling impulses, reading and interpreting social cues, using a procedure for problem solving and decision making, and developing nonverbal and verbal communication skills. Teachers are trained in a 3-day workshop at the beginning of the year, with ongoing support and consultation.

The PATHS curriculum is unusual in the rigor of the research base and its demonstrated effectiveness in both

regular and special education classrooms (Greenberg & Kusche, 1993; Greenberg, Kusche, Cook, & Quamma, 1995). It has been tested in randomized, longitudinal studies with classroom observation components in Seattle-area first- to third-grade classrooms with approximately 60% White and 40% African American students and mainly low- to middle-income families. Positive outcomes include increased fluency and comfort in discussing basic feelings, as well as positive efficacy beliefs around managing and changing feelings. Among students at behavioral risk, teachers noted significant improvements in frustration, tolerance, social skills, task orientation, peer relations, and internalizing behaviors. Investigators mentioned significant variation regarding the level at which the teacher modeled cognitive and behavioral skills, shared emotions, and established an atmosphere of respect for varying beliefs and feelings (Greenberg et al., 1998). However, no outcomes were reported regarding differences by teacher ability or ways in which support staff attempted to bolster teacher skills. Finally, although the program includes generalization activities to be used outside the classroom and materials for families, outcomes generally have not been reported on the impact of nonclassroom and parent materials.

Peer tutoring. Peer tutoring, also called peer-assisted learning, has been used as a classroom-wide intervention aimed at raising achievement and increasing prosocial behaviors. Students are paired in fixed or reciprocal tutor–tutee roles. Primarily implemented in the elementary and middle schools, programs have addressed reading (Fuchs, Fuchs, & Burish, 2000) and mathematics (Fantuzzo, King, & Heller, 1992). Student tutors are trained to structure the tutoring time and use immediate corrective feedback with their tutee. Goals and rewards are built into the tutoring time to help the pair work efficiently and foster mutual motivation. The theoretical basis of peer tutoring is derived from research on the influence of classroom peers on behavior and motivation. It has been argued that in successful tutoring programs, students teach academic skills, model on-task behavior (Topping & Ehly, 2001), and foster academic and social motivation for learning (Rohrbeck, Ginsburg-Block, Fantuzzo, & Miller, 2003).

Given that academically targeted programs have been shown to reduce aggressive behavior (Wilson et al., 2003), the effectiveness of peer tutoring at raising academic outcomes shows promise for improving overall classroom behavior. A meta-analytic review that looked across effect sizes in 90 studies found that, on average, students in peer tutoring made moderate achievement gains (Rohrbeck et al., 2003). The programs were particularly beneficial for younger elementary students, low-income students, and urban students. While much of the research has focused on achievement gains, several studies have shown that peer tutoring is linked with improved behavior (Pigott, Fantuzzo, & Clement, 1986; Wolfe, Fantuzzo, & Wolfe, 1986). For instance, in a study with urban African American peer tutors, groups that were given rewards contingent on academic success were perceived by the teacher as showing lower negative classroom conduct (Fantuzzo et al., 1992).

Teacher consultation (Good behavior game). It has been argued that school counselors' roles should be expanded to include teacher consultation with the aim of increasing teacher capacity in classroom management (e.g., Adelman & Taylor, 2002). Drawing on behavioral consultation models, a counselor identifies the teacher's concern, gathers information about antecedents and consequences of the concern, develops a plan of intervention with the teacher, and determines the outcome of the intervention (Sladeczek, Kratochwill, Steinback, Kumke, & Hagermoser, 2003). A counselor may consult with a teacher to help implement specific programmatic interventions designed to improve classroom behavior. One such program is the Good Behavior Game (Barrish, Saunders, & Wolf, 1969), which draws on the premise that group-based rewards increase the likelihood that peers will be motivated to inhibit negative behavior. To implement the program, the teacher identifies a specific block of time when the game likely will have initial success. Then, the teacher, in consultation with the students, selects negative behaviors to decrease and chooses "activity rewards," such as extra time for free-choice reading. The teacher divides the students into teams, which receive points when they exhibit the predetermined negative behaviors. All the teams can win if they have fewer than the predetermined number of points (Embry & Straatemeier, 2001). The intervention has been found to be well liked by teachers (Tingstrom, 1994).

Embry (2002) offered a thorough review of the Good Behavior Game and its proven effectiveness in diverse classrooms. In short, implementation of the game lowered a range of negative behaviors across grades levels, in multiple settings in the school, and with at-risk populations. For instance, the program was associated with lowered disruptions with fourth graders (Barrish et al., 1969), elementary-age special education students (Darveaux, 1984; Grandy, Madsen, & De Mersseman, 1973), and adolescents (Salend, Reynolds, & Coyle, 1989). In a randomized trial in Baltimore with first graders, the game had the largest effect in reducing the aggressive behavior of students rated as high on aggression prior to the intervention (Dolan, Kellam, & Brown, 1993). Long-term effects of the classroom-centered intervention found that by sixth grade, the first graders who had played the game, relative to the control group, had fewer conduct problems and fewer suspensions (Ialongo, Poduska, Werthamer, & Kellam, 2001). A key ingredient appears to be peer pressure, such that positive

peer norms are set and disruptive behavior is discouraged (see Hegerle, Kesecker, & Couch, 1979).

Playground interventions. Aggressive behavior in schools occurs most frequently in unstructured settings such as the lunchroom and playground (Craig & Pepler, 2000; Craig et al., 2000). Recent attention has been paid to the characteristics of safe and productive playgrounds, and programs targeting these characteristics have been shown to reduce aggression and violence among elementary school students. The characteristics include access to structured activities and an organized space (Bay-Hinitz, Peterson, & Quilitch, 1994), clear communication of rules and expectations (Colvin et al., 1997), sufficient and active supervision (Olweus, 1999), and incentives and consequences for positive and negative behavior (Eddy, Reid, & Fetrow, 2000). Although playground interventions may be imbedded in more comprehensive programs, research demonstrates that targeting these characteristics can reduce aggressive behavior. In one low-income, predominantly African American, urban elementary school, structured and organized games on the playground were associated with higher cooperative play and lower rough physical play over the school year, while active supervision by parent volunteers was associated with higher intercultural interaction (Leff, Costigan, & Power, 2004).

Another research team included a playground intervention in a multicomponent program (Linking the Interests of Families and Teachers; LIFT) in high juvenile crime neighborhoods within a small and majority Caucasian city. Researchers modified the Good Behavior Game (previously described) so students earned armbands from playground staff for clearly identified positive behaviors (toward a whole class reward) and negative behaviors were logged and subtracted from "good faith" points (adding to small group rewards; Eddy et al., 2000). The comprehensive program had a 3-year positive effect on elementary school children with high initial levels of aggression. Younger students had reduced playground aggression and hyperactive/inattentive behaviors, and older students had reduced arrests, delinquency, and drug use (J. B. Reid et al., 1999).

Finally, related to the peer tutoring program previously described, older peers have been trained to mediate conflicts on the playground as a supplement to the supervision by adults. In one well-implemented and evaluated program, older peers received 15 hours of training in recognizing and resolving conflicts, as well as ongoing support from a mediation team and playground supervisors. When eight trained and supported peer mediators were present on elementary school playgrounds in a middle-income, suburban community, there was an abrupt and sustained reduction in physical aggression that lasted for 2 years (Cunningham et al., 1998). Taken together, these intervention studies indicate the effectiveness of a strategy to target the *contexts* in which aggressive behaviors occur, not only the aggressive *individuals*.

Multilevel Programs

Programs designed to target multiple levels at which aggression develops and is impacted have been shown to be somewhat effective in preventing and reducing aggressive behavior in schools. These generally require more resources to implement, as well as more "buy-in" among school personnel, but the trade-off may be benefits across domains of development (e.g., reducing aggression *and* enhancing achievement).

Fast track. Based on research indicating that externalizing problems are multiply determined, the Conduct Problems Prevention Research Group (1999a, 1999b) designed, implemented, and studied a comprehensive school-based program to target risk and protective factors across universal and high-risk groups of first-grade students. The universal aspect of the program included the classroom-based PATHS curriculum addressing emotions, social behaviors, and social problem solving (described earlier), along with basic parent education and skills groups. The targeted program included student social skills groups, academic tutoring, parent–child pair work, peer pair work, and home visits for students identified as behaviorally disruptive (Conduct Problems Prevention Research Group). The universal program was delivered mainly by teachers after an intensive workshop and with regular consultation; the selective program was delivered by family/educational coordinators and paraprofessionals who received extensive and ongoing training and supervision.

This intervention study was unique in its scope and rigor. Researchers matched and randomly assigned 54 schools in diverse communities across the United States to intervention or control conditions, and studied the impact of the universal and high-risk components with classroom observations, as well as teacher, student, and parent reports, over a 3-year period. Initial positive effects were found for classroom climate, on-task behavior, and rule following among the universal population of students, and among parenting, aggressive behavior at school, coping skills, language arts grades, and peer acceptance for high-risk students across four sites (Conduct Problems Prevention Research Group, 1999a, 1999b). Differences were not found by site or student background (gender or race). Limitations to this intervention study include a lack of knowledge of program sustainability over time, the dosage necessary for a positive effect, the reasons why some students do not respond, and the role of school/classroom context in intervention impact. In addition, recent studies

indicate that the long-term consequences for school behavior of this intensive and comprehensive program were less strong than anticipated (Conduct Problems Prevention Research Group, 2004).

Child Development Project. The Child Development Project aims to build "caring communities of learners" in elementary schools (Battistich, Schaps, Watson, & Solomon, 1996). Like the programs just described, the Child Development Project includes activities across multiple levels: (a) the school—principal leadership, schoolwide activities; (b) the classroom—developmental discipline; cooperative learning; values-rich, literature-based reading and language arts curricula, and a phonics-based reading program for struggling readers and, (c) the family—home activities to build home–school communication as well as understanding of family culture. Unlike these programs, however, the Child Development Project is designed not only to address the problem of aggressive behavior in school, but also to create a school *community* that more generally enhances student learning, cooperation, and respect.

Quasi-experimental studies with video observation of implementation quality and a range of student sociodemographic characteristics (ethnicity, income) showed short- and long-term positive results. In high implementation elementary schools, third- to sixth-grade students had lower rates of truancy, theft, substance use, and weapon carrying, and reported more sense of positive school community (Battistich et al., 1996). Follow-up studies indicated that when students in high-implementation elementary schools attend middle school, they had higher achievement and educational expectations, as well as lower misconduct and delinquent behavior than comparison students (Solomon, Battistich, Watson, Schaps, & Lewis, 2000). In addition, the phonics-based reading curriculum alone increased reading achievement for all students, but particularly for non-native English speakers (Battistich, 2000). A significant limitation of this program was that less than half of the schools that implemented the program did so to a high degree of fidelity. However, when implemented well, results indicated the potential importance of a universal emphasis on both academic learning and classroom/school culture as a means toward reducing behavioral problems among all students.

Positive Behavioral Interventions and Supports. Based on a public health model, Positive Behavioral Interventions and Supports (PBIS) emphasizes a three-tiered approach to preventing and addressing disruptive behaviors (Lewis & Sugai, 1999). The first tier (universal) targets all children and adults across the school setting with the idea that that every student needs clear instruction, support, and reinforcement regarding appropriate and inappropriate behaviors in and around the school building (Horner et al., 2001). The second tier (targeted) is geared toward children at risk for disruptive behavior, meaning they have engaged in problem behaviors in the past and have minimal access to protective supports. They are seen as unlikely to respond to universal interventions and in need of secondary-level interventions (e.g., daily report card, functional behavioral assessment) to move them in a more positive direction (Hawken & Horner, 2003; March & Horner, 2002). The third tier (intensive) is designed to provide team-based individualized and comprehensive services for those children with more severe behavioral problems who respond to neither universal nor targeted interventions (see Eber & Nelson, 1997). Across the three tiers, PBIS emphasizes the importance of measuring outcomes and using data for decision making, using practices with evidence of effectiveness, and attending to systems within the school to sustain the program.

The implementation and research data on PBIS is promising. Elementary and middle schools in primarily suburban, middle-income communities have been able to incorporate PBIS into their schools to high standards (e.g., Lewis, Sugai, & Colvin, 1998; Taylor-Greene & Kartub, 2000). Research studies with a pre/post design indicate a 20% to 60% reduction in discipline referrals and suspensions between the year before and the year after full implementation of PBIS (Lohrman-O'Rourke et al., 2000; Luiselli, Putnam, & Sunderland, 2002). These effects have been sustained over 6 years in schools that have continued to implement the program (Taylor-Greene & Kartub). Observational methods demonstrate that lower rates of discipline referrals are related to changes in disruptive behaviors in unstructured school settings such as the playground and hallway (Cushing, in press). What is not known is the ability of PBIS to be implemented to the same degree of fidelity and with the same effectiveness in urban low-income schools where the behavioral issues and school systems may be both qualitatively and quantitatively different from their suburban counterparts.

Final Issues

Although this section demonstrates the range of evidence-based interventions to prevent and reduce aggression in schools, there are several final issues to consider. First, intervention research tends to focus on overt forms of aggression and boys, rather than more subtle forms of aggression or girls. Recent efforts have been made to address the problem of relational or social aggression among girls (see Cappella & Weinstein, 2006; Leff, 2005), but these efforts are preliminary and must be linked with more comprehensive programs. Second, demonstration programs—in particular, those that operate at multiple levels—demand consider-

able resources. There is conflicting evidence regarding the importance of single- versus multiple-level approaches to addressing violence in schools, but research is clear regarding the importance of quality implementation. That said, few intervention studies describe implementation efforts, leaving gaps in understanding of methods for increasing implementation quality with school and community resources. Third, demonstration programs are developed and implemented most frequently in elementary schools, with middle and high schools receiving minimal attention. Although prevention with younger students is critical, given that aggression continues to develop through adolescence, older students deserve systematic efforts to create classroom and school environments in which prosocial behaviors are the norm. Fourth, with some exceptions, these interventions are largely a-contextual without consideration for peer and cultural norms—which may be critical to the effectiveness of a program. Finally, the evidence-based practice movement relies on a process that moves from highly controlled trials to wider dissemination within schools. A more ecologically valid approach to developing an understanding of what works may be an *iterative* process of research and development based not only in theory and research, but also within the school and community context in which the efforts exist.

Recommendations

The school counselor can play an integral role in assisting the school to prevent or address the problem of school violence by providing information and support around the use of evidence-based practices in their schools. However, given the multiple and complex realities of different school communities, there are several steps to consider prior to and during the process of implementing one of the previously discussed programs to maximize the potential benefit. From the research and theory on the development, prevention, and management of aggression in schools, we recommend the following guidelines when attempting to address school violence:

1. Collect and analyze data to understand where, when, and with whom aggression occurs.
   - Use existing datasets (e.g., discipline referrals) or gather new data (e.g., conversations or surveys with school staff).
   - Assess multiple forms of aggression, including physical, verbal, and relational aggression (Leff et al., 2001).
2. Coalesce key personnel and the school organization around the need for intervention within particular settings and/or groups of students.
   - Promote a supportive school climate around the prevention and reduction of aggression (Gottfredson et al., 2004).
   - Build school capacity to initiate and sustain an innovation (e.g., infrastructure and support, resources, and leadership; Sherman et al., 1997).
   - Prepare to integrate elements of the intervention into the structure of the school or setting (e.g., classroom, playground; Heller, 1990; Gottfredson et al., 2004).
3. Help school personnel select empirically supported activities with particular attention to the population with which and context within which the services have been tested.
   - Consider interventions designed to promote change within the individual child, as well as within the social context (e.g., universal, targeted, and indicated levels; Weissberg & Greenberg, 1998).
   - Multiple level programs accompanied by a clarification and communication of norms about behaviors are promising; however, it is more important to implement a less-resource heavy program well than a more-resource heavy program poorly (Durlak & Wells, 1997; Gottfredson et al., 2004; Sherman et al., 1997).
   - Intervene at the appropriate stage of development (e.g., early in the onset of problems for a student or setting) and during sensitive periods, such as transitions during the school day (Tolan, Guerra, & Kendall, 1995; Weissberg & Greenberg, 1998).
4. Monitor the implementation and/or adaptation of those programs or practices.
   - Adapt program content to ethnic and sociodemographic characteristics of students to maximize the potential that it has meaning in their lives, in particular if the program was tested in a demographically different school community than the one in which it will be implemented (Heller, 1990).
   - Provide extensive, quality training of personnel who deliver services, and provide supervision and support for ongoing delivery of services (Gottfredson et al., 2004).
5. Collect data to evaluate the progress of the intervention strategies and make adjustments as needed.
   - Think about the multiple outcomes that may be important to the school and collect data on those outcomes (e.g., different types of aggres-

sion, academic achievement, attendance) from multiple sources (e.g., teachers, students, school data).

- Allow sufficient time for the activities to work before making major adjustments to the intervention strategies; anticipate that the strongest results will be for the students and settings exhibiting the most problems at the start.

XLII
SUBSTANCE ABUSE

CHRIS WOOD AND LISA HINKELMAN
The Ohio State University

Introduction

Adolescent substance use and abuse is a significant concern in American society. Students in middle school and high school are using illicit substances, including marijuana, amphetamines, alcohol, and cigarettes at alarming rates. School counselors are likely to encounter students dealing with substance use and abuse issues on a regular basis. Doweiko (2002) discusses childhood and adolescence as a time when individuals are especially vulnerable to developing substance abuse disorders. This chapter is designed to provide the reader first with an overview of the prevalence, recent trends, and contributors to adolescent substance use and abuse. Next, information about how the school counselor can intervene in substance abuse situations is included, followed by an introduction and overview of the use of Motivational Interviewing (MI) in the school setting.

Using a case example, the reader will learn to identify a student's level of change within the stages of change model. Next, the principles of MI and the research that supports MI as an effective technique for working with substance use disorders are discussed. Finally, the reader will be provided with strategies for dealing with student resistance and with information on selecting effective treatment programs.

Prevalence

According to the Substance Abuse and Mental Health Services Administration (SAMHSA; 2004), nearly 19.5 million Americans, or 8.2% of the population, over the age of 12 currently use illicit drugs. The percentage of American youth who currently use illicit drugs is 11.2%. The National Institute on Drug Abuse (NIDA) reported in their 2004 Monitoring the Future Study that 51% of the population uses illicit drugs at some point throughout their lifetimes. Nearly 40% of 12th graders reported having used marijuana during the previous 12 months, 10% have used amphetamines, and 48% have used alcohol. SAMHSA also reported that approximately 10.9 million people between the ages of 12 and 20, or 29% of this age group, report drinking alcohol, with 19.2% of this age population engaging in binge drinking, and 6.1% identifying as heavy drinkers. Additionally, approximately 24% of adolescents ages 12 to 17 report smoking cigarettes, with 15% of the adolescent population classified as nicotine dependent (Johnston, O'Malley, Bachman, & Schulenberg, 2005). With this level of prevalence, it is likely that school counselors will encounter many students who are struggling with addictive behaviors.

Gender and Ethnicity

Much of the research that has been conducted on substance abuse has focused primarily on men and boys. Additionally, of the limited research that has specifically examined gender differences in substance use and abuse, ethnic minority girls have been underrepresented (Wallace et al., 2003). A recent national study on adolescent drug use found that use was lowest among African American and Asian American adolescents and highest among White students. Hispanic adolescents had rates of illicit drug use similar to, but slightly less than, their White counterparts had (Johnston et al., 2005).

Males reported higher rates of illicit drug use than females with specific differences in use of smokeless tobacco, steroids, and alcohol. Adolescent boys and girls have nearly identical rates of cigarette smoking (Johnston

et al., 2005). Over the years, there has been a convergence in the drug usage rates of boys and girls with the prevalence of use becoming very similar among both genders. Researchers speculate that part of this is due to changes in gender role expectations and acculturation levels of young girls in present society (Wallace et al., 2003). Previously, it was considered "unladylike" for girls to smoke, drink, or engage in illicit drug use. More recently, the social taboos regarding expectations of femininity have changed, allowing girls increased opportunities to engage in activities and behaviors that were previously deemed inappropriate for their gender. While this change has resulted in increased opportunities for girls in a variety of arenas, it has also resulted in more girls choosing to engage in the use and abuse of licit and illicit substances.

Recent Trends

An understanding of the recent trends in adolescent substance use and the factors related to illicit drug use is imperative for a school counselor's effective intervention with substance abusing students. The usage reports of the adolescent substances use have remained relatively consistent over the past few years, maintaining a level lower than their peak in the early 1990s. However, there have been slight decreases reported by adolescents in the use of "any illicit drug" and similar decreases in the accessibility and use of drugs such as LSD, heroin, Rohypnol, and Ecstasy (Johnston et al., 2005). Slight increases were reported in the use of psychotherapeutic drugs taken nonmedically, including pain relievers, tranquilizers, stimulants and sedatives (SAMSHA, 2004) and significant increases were reported in the use of inhalants and OxyContin (Johnston et al., 2005). This trend indicates that adolescents are using substances that are readily available to them and that may be found in their home medicine cabinet or at their local grocery store. Accessing a family member's painkillers or purchasing items such as spray paint, cans of whipped cream, and other inhalants may not be readily apparent to parents and guardians, and as a result, substance use may not be identified for some time. School counselors can assist in training parents and families about these recent trends and help them to identifying the substances that might be in their homes that have the potential to be abused.

Contributors to Adolescent Substance Abuse

Children and adolescents experiment with alcohol and illicit substances for a variety of reasons. Adolescents report using substances as a way to experiment, to feel good, and to enhance social activities (Parks & Kennedy, 2004). Youth also attribute substance use to the influence of friends, the need for pleasure, and the personal curiosity associated with trying something new (De Micheli & Formigoni, 2002). While some adolescent substance experimentation appears somewhat innocuous and part of the typical adolescent experience, others report using substances as coping mechanisms for handling depression (Boys, Marsden, & Strang, 2001).

Researchers have attempted to understand the situational, familial, and environmental factors that contribute to adolescent substance use and abuse. Nunes and Parson (1995) reported that multiple factors impact adolescent substance abuse, including poor parent–child relationships; psychiatric disorders, especially depression; family and peer substance use; low academic motivation; behavioral problems; early cigarette use; low self-esteem; single-parent or stepparent families; and a high number of family stressors. The early use of tobacco and alcohol was also found to predict future substance use as well as accelerate the substance use by adolescents (Clark, Cornelius, Kirisci, & Tarter, 2005). Bailey and McCloskey (2005) found that adolescent girls with a history of sexual abuse were more likely to abuse illicit substances than girls who had not been previously sexually abused. Similarly, boys are also negatively impacted by abusive environments, and such environments can influence their future likelihood of substance use (Kirisci, Dunn, Mezzich, & Tarter, 2001). Specifically, researchers (Clark et al.; Kirisci et al.) have found that parents with a substance abuse diagnosis were more likely to abuse or neglect their children and that boys who were neglected as children and young adolescents were more likely to be substance abusers in late adolescence and early adulthood (Kirisci et al.).

Parents can be very influential in the lives of their adolescent children as it relates to substance use (Kelly, Comello, & Hunn, 2002; King, Vidourek, & Wagner, 2003; Nash, McQueen, & Bray, 2005), and children identify their parents as the people that have talked to them most about drug use (Kelly et al.). Adolescents who have a positive family environment have fewer friends that drink alcohol and have increased self-efficacy for refusing to drink alcohol (Nash et al.). Additionally, researchers have found that parents who spent a greater amount of time with their children were more likely to have children that did not use drugs. Conversely, parents who spent little time with their children and parents who use illicit substances are much more likely to have children who use drugs and alcohol (King et al.).

The school environment and school related factors are also related to adolescent substance use. D. J. Eitle and T. M. Eitle (2004) found that the school climate impacted the rates of illicit drug issues at the school. Specifically,

schools that have students who are not committed to the mission of the school, that have predominately White students, that lack resources for students, and that have lower credentialed teachers and staff have a higher percentage of illicit drug offenses than other schools (Eitle & Eitle). Student truancy rates and grade point average are also predictors of drug use (Hallfors et al., 2002). Hallfors and colleagues discovered that the marijuana use of both 8th grade students and 12th grade students was correlated to their truancy rates and grade point averages. Students who were frequently truant and who had grade point averages below 2.5 were more likely to use illicit substances. Conversely, students who planned to attend college were less likely to use some illicit substances including cocaine, heroin, stimulants, and hallucinogens (Johnston, O'Malley, & Bachman, 2003).

Protective Factors

While there are numerous risk factors associated with adolescent substance abuse, there are several protective factors that help youth resist substance use and abuse. Risk factors, like those just mentioned, are antecedents that increase the probability that that substance abuse will exist, while protective factors serve as moderators and can reduce the effects of the exposure to risk (Hawkins, Van Horn, & Arthur, 2004). The goal is to build in enough protective factors in the lives of youth at risk to offset the exposure to the risk factors.

Clinton-Sherrod, Sobeck, Abbey, Agius, and Terry (2005) found that there are protective skills that adolescents can develop through their interactions with family, friends, community, and school that help youth abstain from using illicit substances. Specifically, their research found that African American sixth-grade students who had developed good decision-making skills, had higher self-efficacy, had lower peer pressure susceptibility, and had attitudes about school that were more positive were less likely to use substances. Other individual factors found serve as protective factors in youth substance abuse, including the ethnic and racial identity of urban African American young adults (Brook & Pahl, 2005). Brook and Pahl's research on African American youth found that adolescents with high levels of ethnic and racial identity, high identification with African American friends, and high valuation of their nuclear and extended families were able to resist the use of illicit substances.

As previously noted, individual characteristics can serve as protective factors; however, community and familial characteristics can also be protective factors in the lives of adolescents (Hays, Hays, & Mulhall, 2004). Communities that have appropriate and available child care, opportunities and rewards for prosocial involvement, and members with high social skills also enjoy a reduced rate of substance use (Hawkins et al., 2004; Hays et al.). Parenting style has also been found to relate to youth substance abuse, specifically, parenting that is authoritative and warm with higher levels of monitoring and lower levels of coerciveness is most effective in reducing adolescent substance use (Hays et al.).

School counselors are in a unique position to impact families and communities through collaboration with other school professionals including social workers, psychologists, nurses, and administrators to provide training and resources to parents and community members on the importance of protective factors in the lives of children. Through these strength-based collaborative efforts, school counselors can work to build resilient schools, families, neighborhoods, and communities with an emphasis on the strengths that an individual or family possesses rather than on the risk factors or deficits that are present. In this way, the school counselor can effectively serve as a resource and a liaison between the school, family, and community (McLaughlin & Vacha, 1993).

Prevention Efforts

In recognition of the prevalence, trends, and contributors to adolescent drug and alcohol use, the United States federal government allocated resources for the prevention of drug use among America's youth. In 1994, The Drug Free Schools Act was expanded into the Safe and Drug Free Schools and Communities Act. This Act was authorized under Title IV of the *Elementary and Secondary Education Act* (ESEA) of 1965 and was designed to provide local, state, and national funding for research-based drug and violence prevention programming in elementary and secondary schools and institutions of higher education. According to the White House Office of the Press Secretary (U.S. Department of Health & Human Services, 1998), the Safe and Drug-Free Schools Program provides support for prevention programming to 97% of America's school districts. Currently the Safe and Drug Free Schools and Communities Act is administered by the U.S. Department of Education under the No Child Left Behind Act of 2001 (P. L. 107-110). This effort is focused on comprehensive programming to promote safety, development, and positive outcomes for students while decreasing the use of alcohol, tobacco, and other drugs.

Through the administration of community service grants, governors' grants, and state formula grants, individual states can apply for funds to combat drugs and violence in their schools. Nationally, discretionary grants are available for through the Drug-Violence Prevention National Programs and include prevention programming for college

campuses, school-based drug-testing programs, alcohol abuse programming, mentoring grants, and several additional drug and violence prevention programs (U.S. Office of Management and Budget and Federal Agencies [USOMB & FA], 2006).

In 2002, the U.S. Department of Education created a Safe and Drug-Free Schools office that is home to all federal safe schools, crisis response, alcohol and drug prevention, character education, and health and wellness programs, including Safe and Drug-Free Schools National Programs, Safe and Drug-Free Schools State Programs, Physical Education, School Counselors, School Emergency Response to Violence, Character Education, Civic Education, National Clearinghouse for Education Facilities, and Correctional Education ("Safe and Drug-Free Schools Office Created," 2002).

The Safe and Drug Free Schools Office provides state grants that are specifically designed to "help create and maintain drug-free, safe, and orderly environments for learning in and around schools" (USOMB & FA, 2006). These state grants are awarded to school districts with "research based approaches to drug and violence prevention to reduce youth crime and drug abuse" (USOMB & FA). Since 2002, this program has failed to demonstrate effectiveness in reducing youth drug use and violent crime, and has been deemed "ineffective" (USOMB & FA) by the U.S. government. The assessment of the program indicates that the funds are spread too thin to be effective, and that program is currently not performing. Thus, at the outset, there is little evidence that this government initiative has been effective in making an impact on the actual substance use of teens.

Role of the School Counselor in Intervention

In addition to the various governmental funding opportunities for substance abuse prevention programs, schools and communities also seek ways to reduce the substance abusing behavior of their students and the school counselor is often expected to support and implement substance abuse prevention and intervention programming. Lambie and Rokutani (2002) asserted that the school counselor has a unique opportunity to work closely with students, parents, teachers, and administrators and can use these relationships and access to intervene early in cases of suspected substance abuse. In order for the school counselor to effectively intervene in such situations, he or she must first understand the scope of the problem (Lambie & Rokutani). In addition to the contributors to and predictors of substance abuse mentioned previously, school counselors should be aware of additional warning signs and symptoms of substance abuse including changes in students' moods and behavior, drops in grades, truancies (Lambie & Rokutani), and increased sexual activity (Hallfors et al., 2002).

Lambie and Rokutani (2002) identified four tasks of school counselors in working with students with possible substance abuse issues, including identifying the warning signs of substance abuse, working with the student to develop an effective therapeutic alliance, supporting the family in order to promote change, and acting as a liaison between the student, family, school, and community agencies and/or treatment programs. The school counselor should be equipped with skills and confidence to intervene when he or she suspects that a student is abusing drugs or alcohol.

School counselors intervening with a student who is using drugs or alcohol need to be aware of the unique issues that exist in schools. The school setting does not provide the ideal environment for intensive substance abuse treatment. Moreover, school counselors do not have the time to provide such treatment given the many demands of their job. However, the school counselor can effectively support students, provide brief interventions that will assist students abusing substances, and provide linkages between the adolescent and the other systems in which he or she functions (Lambie & Rokutani, 2002). In doing this, the school counselor can increase the likelihood that students will enter and adhere to treatment.

There are times when students will disclose substance use or abuse to the school counselor and ask the school counselor to maintain the confidentiality of the student. The counselor's role in a situation where there are ethical or legal implications can be difficult to define and is often based upon state laws, school district policies, and interpretations of various ethical codes. While federal law protects the confidentiality of minors seeking drug or alcohol treatment (Fisher & Harrison, 2005), school counselors may not always be protected by this law. School counselors are not always considered "mental health professionals," and because they are not providing alcohol or drug diagnosis and treatment services, the federal regulations that govern confidentiality regarding substance abuse treatment might not apply uniformly to all school counselors (Fisher & Harrison).

While students are the school counselor's primary obligation, parents of minor students have legal rights to knowledge and information about their child. A school counselor has an ethical obligation to the student but a legal obligation to the parent (Remley & Herlihy, 2005). In order to work most effectively with students, the school counselor must develop an effective therapeutic relationship with the children. In adolescents, this rapport is gen-

erally fostered through a commitment of confidentiality on the part of the counselor (Remley & Herlihy), which has obvious limits. Remley and Herlihy and Stone (2005) suggested taking proactive steps regarding the handling of confidential information to minimize the negative impact on both students and parents.

Stone (2005) suggested informing students, parents, teachers, and school personnel about the limits of confidentially before it becomes an issue; informing teachers that the school counselor will consult with them when it is necessary and in the best interest of the child; and working with students to encourage them to share information with their parents, perhaps with the school counselor present as a support. It is also very important for school counselors to be knowledgeable about the school board policies; local, state, and federal regulations; and professional codes of ethics that govern their profession.

School counselors require an approach that takes into account the role of the school counselor and is consistent with the school counselor's unique position as a helping professional operating in the school setting. MI is an innovative approach school counselors can utilize in working to help students change problematic behaviors.

Motivational Interviewing

MI is a counseling approach developed by Miller and Rollnick (1991, 2002) that can assist students with the process of change. While originally conceptualized as an approach for working with individuals with addictive behaviors, the approach has been used successfully with a range of behavioral changes including physical exercise (Harland et al., 1999), weight reduction (Smith, Heckemeyer, Kratt, & Mason, 1997), bulimia (Treasure et al., 1999), marijuana use (Stephens, Roffman, & Curtin, 2000), and alcoholism (Project Match Research Group, 1997, 1998). Burke, Arkowitz, and Menchola (2003) conducted a meta-analysis of 30 controlled clinical research trials that investigated MI or Adaptations of Motivational Interviewing (AMI). Overall, they determined that the research supported the efficacy of AMIs for problems involving alcohol and drugs, as well as diet and exercise.

Using MI in Schools

MI is an ideal approach for school counselors to use in counseling students who exhibit addictive behaviors. The brief nature of MI poses a time/cost-effective strategy given the large student-to-school-counselor ratio that exists in many school settings. Moreover, since MI is designed to build in individuals the capacity for change rather than to be an actual treatment modality, the MI approach is consistent with the role of the school counselor in helping the student seek treatment rather than actually providing ongoing counseling for addictive behaviors. Lastly, the guiding principles of MI help to differentiate the school counselor from other educators/administrators who may have a more confrontational or disciplinarian orientation with the student.

The use of MI in schools requires a shift in theory and approach to working with students who use and abuse substances. The focus of MI is centered upon how motivated the people are to change as opposed to how resistant they are (Tevyaw & Monti, 2004). Adolescents are often challenging to work with in a therapeutic relationship due to their developmental level and their need for autonomy (Lambie & Rokutani, 2002); therefore, the use of a confrontational intervention can serve to completely disengage the student. Lambie (2004) posited, "A practical school counseling approach needs to provide strategies that in a brief amount of time would assist students who may be unmotivated to change" (p. 268).

MI utilizes a harm reduction approach, not an abstinence based approach, and the interventions are tailored specifically for each individual student and his or her present situation and level of motivation to change (Tevyaw & Monti, 2004). It is a brief intervention that is flexible and emphasizes the freedom of choice of the student (Lawendowski, 1998). Lawendowski asserted, "A brief, motivational intervention consisting of just one or two sessions holds promise as a treatment for adolescents with substance abuse problems" (p. 41). MI and motivational enhancement therapies are effective in decreasing substance use and increasing treatment engagement in adolescents (Tevyaw & Monti).

To counsel students with addictive behaviors, it is first necessary to have an understanding of both (a) how addictions develop and (b) how people change behaviors. The process of developing addictions and the process of changing addictive behaviors involve the same stages of change. With an understanding of the stages of change, school counselors can utilize MI techniques specific to the appropriate stage for the student. In this fashion, school counselors can facilitate a student's progression toward positive behavioral change.

Stages of Change

Prochaska and DiClemente (1982) developed a Transtheoretical Model (TTM) of behavioral change. This model posits 6 phases in the process of intentional behavior change that can be described as the Stages of Change (DiClemente, 2003). These stages are (a) precontemplation, (b) contemplation, (c) preparation, (d) action, (e) main-

tenance, and (f) termination. Movement through these stages of change is generally recursive and cyclical (see Figure 42.1). Each of these stages has unique characteristics. There is an identifiable "goal" to be achieved in each specific stage. Similarly, students engaged in the process of change must successfully complete the necessary tasks of each stage in order to successfully progress toward the subsequent stage. Figure 42.2 describes the student goals for each stage of change and the corresponding school counselor tasks for working with students in that stage. School counselors assisting individuals with the process of change can benefit from being aware of the stages of change, the goals for each stage, and the necessary tasks for each of the 6 stages.

Precontemplation

As Figure 42.1 illustrates, precontemplation is the stage prior to entering the cycle of change. Students in the precontemplation stage do not feel the need to change current patterns of behavior or do not see convincing reasons to consider behavioral change. Or they do not believe that the negative repercussions of the current behavior outweigh the costs of actively engaging in behavior change. "As long as the current pattern of behavior seems functional for the individual or no compelling reason arises to disrupt this pattern, an individual can remain in precontemplation for extended periods of time, even a lifetime" (DiClemente, 2003, p. 26).

Students in precontemplation may seem the most frequently encountered by school counselors. Generally, students in the precontemplation stage (precontemplators) are seen as highly "resistant" or unwilling to respond to counseling interventions. Conceptualizing students in the precontemplation stage as one of the four categories of precontemplators can assist school counselors in using more facilitative methods for helping students move toward change.

There are four types of precontemplators: (1) reluctant, (2) rebellious, (3) resigned, and (4) rationalizing (DiClemente, 1991; DiClemente & Velasquez, 2002). Each type of precontemplator is characterized by the primary way in which he or she avoids considering change.

Reluctant precontemplators are students who lack full awareness of their problematic addictive behavior and are therefore passively resistant. These students do not wish to risk change, as they do not see any potential benefits to changing their current status quo.

In contrast, rebellious precontemplators are actively resistant to change. Students who are rebellious precontemplators often have strong feelings against change and may have a heavy investment in their current addictive behavior. These students do not like being told what to do

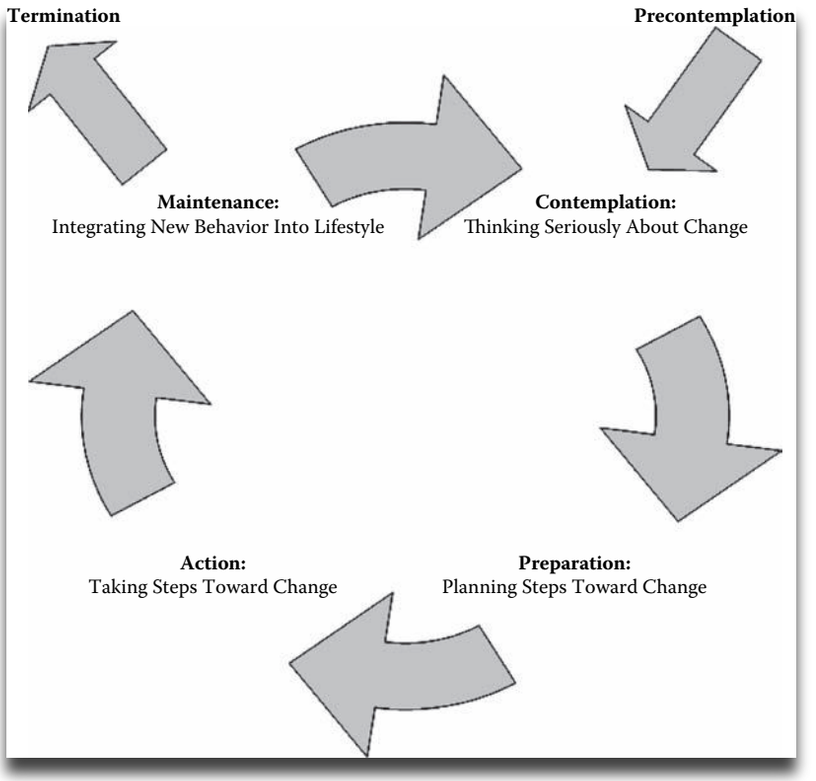

Figure 42.1 The Cycle of Change
Adapted from DiClemente (2003).

Stage	Goal for Student	School Counselor Task
Precontemplation	Gaining awareness of the reasons for change; seriously considering possibility of change	• Increase student awareness of the reasons for considering change • Explore internal and environmental influences on maintaining the status quo
Contemplation	A reasoned evaluation that increases a student's commitment to change	• Help student weigh pros & cons of change • Help student tilt the decisional balance scale in favor of change
Preparation	A clearly articulated plan for change with sustaining student self-efficacy	• Assess the student's commitment to the change process • Help the student develop a plan for change that he/she believes has a strong likelihood for success
Action	Continued implementation of plan for change	• Support and affirm student's continued efforts toward change • Help student revise plan for change as necessary
Maintenance	Sustained new behavior that is mutually exclusive of previous behavior	• Reinforce student's commitment to new choices/lifestyle • Help student recover from setbacks and continue building on partial successes

Figure 42.2 The Stages of Change. Based on the work of DiClemente (2003) and Miller and Rollnick (2002).

and may even be hostile toward the proposal of a specific strategy for change.

Resigned precontemplators lack the energy to invest in change and are prepared to accept that their current behavior is inevitable. For these students, the problem seems overwhelming and the barriers to change are too great to warrant an investment of time or energy into the change process.

The fourth type of precontemplator is the rationalizing precontemplator. "These clients are not considering change because they have figured out the odds of personal risk, or they have plenty of reasons why the problem is not a problem or is a problem for others but not for them" (DiClemente, 1991, p. 193). Students who are rationalizing precontemplators sometimes like to "debate" their rationale for their current behavior—thus reinforcing their position against change.

The primary goal for the precontemplation stage is for the student to seriously consider the possibility of change. Since there has been little or no consideration of change of behavior in the foreseeable future, reaching this goal can be a formidable achievement. For the precontemplating student to envision change as a possibility requires successful completion of the major tasks in this stage.

The necessary tasks in the precontemplation stage include increasing student awareness of the need to change. Multiple internal and environmental influences impact the student reasoning for considering change: social pressure, human development, relationships, values, economic pressure, and so forth. Consideration of the current behavior within the context of these influences can compel a student to explore the possibility of changing current patterns of behavior.

Increasing concern about the current pattern of behavior is an important task for the precontemplation stage. This task involves gaining an awareness of potential reasons for change as well as those factors that may positively or negatively impact the student's ability to even begin to consider change.

Instilling hope is perhaps the most profound task for the precontemplation stage. This means exploring the barriers to change and generating productive strategies for overcoming such obstacles. Students in the precontemplation stage may lack hope due to previously unsuccessful change attempts in the current pattern or other patterns of behavior. It is important for the student in this stage to realize that a setback in the change process is expected and inherently different from a complete failure.

Contemplation

In the contemplation stage, the student is weighing the risks associated with change against the potential benefits. This analysis becomes a period of instability for the student. Stu-

dents may struggle with ambivalent or confusing thoughts and feelings about a given behavior pattern as they consider the possibility of change. "The contemplation stage involves a process of evaluating risks and benefits, the pros and cons of both the current behavior pattern and the potential new behavior pattern" (DiClemente, 2003, p. 28).

Students in the contemplation stage are not yet ready to actively commit to the process of change. They are still gathering information and considering options. "Contemplation is the stage when clients are quite open to information and decisional balance considerations. Yet it is also the stage where many students are waiting for the one final piece of information that will compel them to change" (DiClemente, 1991, p. 195).

The goal for this stage, then, is a thoroughly reasoned evaluation that reinforces a student's decision to change. This evaluation should comprise the carefully considered risks and benefits of change. It is important for school counselors to remember that this goal involves an awareness of both sides of the change issue (costs and benefits) because failing to explore either side may hinder the accomplishment of the goal and tasks for the contemplation stage and create further ambiguity for the student.

The task for the contemplation stage is to conduct a thorough analysis of the advantages and disadvantages of the current behavior. This analysis needs to include both the affective and cognitive rewards of the current behavior and the stake involved in change. At the same time, the student needs to fully realize the costs of continuing the current behavior and the potential return on the investment in an endeavor to change. Again, it essential for the school counselor to help the student see the advantages as well as the disadvantages of the current behavior. Focusing only on the disadvantages of the current behavior (as traditional substance abuse models have done) may force students to oppositionally side with the advantages and hinder progression toward other stages.

Preparation

Students in the preparation stage are ready to make a change in the near future. "Preparation takes you from the decisions you make in the contemplation stage to the specific steps you take to solve the problem during the action stage" (Prochaska, Norcross, & DiClemente, 1994, p. 146). The decisional balance in the contemplation stage has been tipped in favor of change and students in this stage are determined to make an attempt at change.

The primary goal for the preparation stage is to formalize a plan of action. The plan of action needs to be a specific, detailed list of the steps necessary to engage in active progress toward change. The plan of action must include those crucial elements necessary to continue the student's initial energy toward action.

Inherent in a plan of action are several critical elements. Students must believe in the feasibility of the plan. They need to see the plan as possessing a strong likelihood for bringing about the desired outcome (the new behavior). Moreover, students need to believe in their own ability to successfully engage in the steps necessary to complete their plan of action. The tasks of the preparation stage involve reinforcing the students' commitments to change and helping them determine the best plans of action.

As part of the task of developing a plan of action there are several important considerations. The student's previous experiences with change should be considered to strategize a plan that has optimal potential for success. Similarly, considering the potential difficulties that could be encountered during the plan is also useful to prepare for action. Finally, as mentioned previously, the student's courage and competency to be successful in the plan are key components of the student's potential to implement any plan of action.

Action

The action stage is the implementation of the plan generated in the preparation stage. In the action stage, students make the move toward altering their behavior. This stage of change requires the greatest commitment of time and energy. For these reasons, this stage is also characterized by an attraction to the old patterns of behavior. It is often easier to return to the previous behavior than to follow through on the plan and begin to sustain a new behavior.

The goal for this stage is to establish a new pattern of behavior. In addition to the major task of implementing the plan of action, additional tasks include sustaining commitment in the face of obstacles to the plan and revising the plan as necessary in order to maintain the enterprise of change.

Maintenance

As Figure 42.1 represents, maintenance is the final stage before exiting the change process. In this stage, "the new behavior must become integrated into the lifestyle of the individual" (DiClemente, 2003, p. 29).

The maintenance stage is distinguished by the clear absence of the previous behavior and the sustained presence of the new behavior. There may still be, however, the urges and temptations to return to the previous behavior. "In the maintenance stage the person works to consolidate the gains made during the action stage and struggles to prevent relapse" (DiClemente & Velasquez, 2002, p. 212).

It is important to note that relapse is not a collapse of the change process. People often "recycle" through one or more stages before successfully negotiating the maintenance stage and exiting the change process into termination.

Success in the maintenance stage allows the new behavior to become "automatic" and the new "status quo" (DiClemente, 2003). Ultimately then, the student is able to exit the process of change (termination), with the new behavior as an integrated part of a new lifestyle.

Termination

Termination is the final exit from the process of change. This is not so much a stage as such but rather a new state of being where a new behavior has replaced the old behavior, and in fact, it would take a substantial amount of effort to go back to the old behavior. In reference to addictive behaviors, this state is sometimes referred to as "recovery." The goals and tasks of termination focus on the new way of being that does not include the previous behavior. "The entire gestalt of life now supports a new lifestyle committed to not engaging in the addictive behavior" (DiClemente, 2003, p. 201).

The preceding discussion of the stages of change addresses primarily the change process for addictive behaviors. As may already be apparent, however, the stages are indicative of any behavioral change. This process also applies to other behaviors that may be problematic for students, such as absenteeism, procrastination, bullying, and other achievement related behaviors. The remainder of this chapter explains in detail the tenets of MI. The following case example demonstrates how school counselors can identify the stages of change in the TTM and practically utilize MI with substance abusing students.

Case Example

Billy is a 16-year-old high school junior who was recently caught drinking at a school football game. When Billy returned from a one-week suspension, the principal asked the school counselor to speak to Billy and determine if Billy will seek counseling for his "problem." Before speaking with Billy, the school counselor gathers more information from Billy's school records. In the 9th grade, Billy was an honor student but his grades began to slip in the 10th grade, and he is currently failing two of his six classes according to his most recent progress report. Also noteworthy are the teacher comments on his progress reports and final grades. For 9th grade, teachers' comments included "Pleasure to have in class" and "Works conscientiously." In subsequent years, the teacher comments changed to "Work consistently lacks effort" and "Assignments not completed." School records also show an address change indicating that Billy moved to live with his mother at the start of 11th grade.

Case Example and the Stages of Change

This case example can be used to demonstrate how a school counselor can use the TTM stages of change to conceptualize work with a student. This conceptualization can help a school counselor understand Billy's situation and develop a strategy to help him. What stage(s) of change is Billy negotiating?

Billy has not come to see the school counselor voluntarily. Because he has not come to see the school counselor of his own accord, it seems unlikely that he will want to discuss treatment options for drug/alcohol. Most likely, Billy is in either the precontemplation or the contemplation stage. Perhaps the following exchange between Billy and his school counselor will help illuminate the stage of change regarding his behavior.

Billy: I don't see what the big deal is, everybody drinks at football games, I just happened to get caught.

School counselor: So one difference between you and your classmates is that your drinking has started to cause you some negative consequences.

Billy: Well, the suspension's not really that big a deal, it's my first one ever. It's just a matter of being in the wrong place at the wrong time.

School counselor: Getting caught was just a matter of bad luck and had nothing to do with your behavior.

Billy: Pretty much, I mean, most people don't actually bring their stuff to the game they drink before.

School counselor: So, another difference between you and some of your classmates is that you take alcohol with you to school events.

Billy: Yes, but I don't do it all the time.

Note that for every statement the school counselor makes, Billy takes an opposing perspective. This dialogue suggests that Billy is in the precontemplation stage. Although he does hint at some of the drawbacks of his behavior, he has convinced himself that change is unnecessary. For these reasons, Billy would most aptly be categorized as a rationalizing precontemplator.

Understanding the stage of change for Billy's problematic behavior allows the school counselor to select a strategy and specific techniques. The general principles of MI (Miller & Rollnick, 1991, 2002) provide a guiding character as well as specific strategies for school counselors to use in helping students with addictive behaviors in the different stages of change. Following these principles and the specific strategies

for the stages of change will assist school counselors in helping students toward changing problematic behaviors.

MI posits four guiding principles to underscore the school counselor's orientation toward the student. These four principles underscore the character of the MI approach and the subsequent strategies for each stage of behavioral change. The principles are (a) express empathy, (b) develop discrepancy, (c) roll with resistance, and (d) support self-efficacy.

Express empathy. The first principle is to consistently express empathy immediately and throughout the change process. The emphasis should be on understanding the student's perspective and be free of blame or judgment. While a school counselor may not agree with the student behavior or approve of student choices, it is still possible to maintain a climate of acceptance.

An overall climate of acceptance facilitates change. Conversely, judgment and blame tend to immobilize the change process. A good way to think of this is to realize that a climate of acceptance frees people to change rather than forcing them to devote energy toward resisting judgment. School counselors need to realize that the school setting in general is not a climate of acceptance and that students (especially those with problematic behaviors) often feel judged by the adults in a school setting.

Related to the notion of acceptance is the understanding that ambivalence is normal and even a healthy part of the change process. "Ambivalence is accepted as a normal part of human experience and change, rather than seen as pathology or pernicious defensiveness" (Miller & Rollnick, 2002, p. 37). Often, ambivalent feelings and thoughts are seen as unhealthy manifestations of unwillingness to engage in positive change—"denial" or "resistance." An important concept of MI, however, is to view ambivalence as a normal part of the change process—to be respected with empathy as with all student experiences and perspectives. Understanding and accepting a student's ambivalence about change then becomes an essential component of being an empathic school counselor.

The principle of expressing empathy is demonstrated using counseling skills. Counseling skills are used to develop an awareness and understanding of student experiences. Through skillful reflective listening, the school counselor is able to step into the student's phenomenal space and thus empathically share his or her perspective. Moreover, counseling skills are also used to express the empathic understanding of student perspective through paraphrasing of messages and feelings.

Consider the opportunities for expressing empathy with Billy, the student described in the case example. Imagine that Billy is expressing ambivalence over his problematic behavior.

Billy: Well, I would like to do better in school, but I would hate to give up all the good times at parties with my friends.

School counselor: Part of you is worried that your excessive drinking and partying are creating difficulties for you at school and part of you can't seem to even imagine not going out drinking with your friends.

While other empathic statements are certainly possible, the school counselor's response provides an example of skillful reflective listening that expresses understanding of the student's perspective.

Develop discrepancy. The second principle that underlies MI is to develop discrepancy between a student's present behavior and his or her goals and values. It is important to note that the school counselor is to "develop" or "amplify" this discrepancy as initiated by the student and within the context of the student's perspective—and not to artificially "create" the discrepancy by imposing the school counselor's perspective or value system. In one sense, the school counselor is helping the student to identify and clarify the student's personal goals and values. Concurrently, the school counselor is helping to bring to the awareness of the student, the conflict between the student's current behavior and student's preferred state of being.

This discrepancy is of course the motivation for change. In order for change to occur, students must be aware of the discrepancy between their current behavior and their desired self. Moreover, it is the awareness of this discrepancy and the belief in their ability to successfully bring about change that fuels student energy to actively continue the process of change.

In utilizing the principal of developing discrepancy, the school counselor places the responsibility for change on the student. "When Motivational Interviewing is done well, it is not the counselor but the client who gives voice to concerns, reasons for change, self-efficacy, and intentions to change" (Miller & Rollnick, 2002, p. 39).

In the case example, the school counselor's last paraphrase to the student is an example of beginning to develop discrepancy.

School counselor: Part of you is worried that your excessive drinking and partying are creating difficulties for you at school and part of you can't seem to even imagine not going out drinking with your friends.

Here, the school counselor is using a paraphrase of message from the student and structuring the paraphrase so as to highlight the student concerns about his changing his present behavior. It is important to note the nonconfrontational style of the school counselor response.

Billy: I mean I know school is important and all that—but these are my last two years of high school and I don't want to miss out on anything.

School counselor: Tell me what is important to you about school.

Billy: Well I want to graduate on time. Also I'd like to go to college and eventually get a good job.

School counselor: So passing your classes and graduating with your classmates is something you value. You'd like to go to college and you see success in school as helping toward that. Tell me about the other values you mentioned, partying and friends.

Billy: I love to hang out with my friends. Most of us drink, but I guess it doesn't always have to be about that.

It is important to remember that ultimately the reasons for change come from the student, not the school counselor. The school counselor is helping the student see the discrepancies between the student's present behavior and the student goals or values. "When Motivational Interviewing is done well, it is not the school counselor but the client who gives voice to concerns, reasons for change, self-efficacy, and intentions to change" (Miller & Rollnick, 2002, p. 39).

Roll with resistance. The third foundational principle of MI is to "roll with resistance" (Miller & Rollnick, 2002). School counselors sometimes conceptualize resistance as a quality in the student—an unwillingness to move toward positive growth. In the MI approach, however, resistance is more appropriately conceptualized as a function of the school counselor–student dynamics. In one sense, resistance is created by confrontational encounter with another person or an interaction that engenders defensiveness on the part of the individual.

One way to deal with resistance or defensiveness is to try to overpower it with convincing arguments. This approach may just cause the student to become increasingly entrenched in his or her present position. Another approach, however is to avoid arguing or trying to convince the student of the need to change—but rather to roll with resistance and allow the student to drive the impetus for change.

Rolling with resistance calls for a school counselor to take several stances with a student. First, the school counselor should not argue for specified change or try to convince the student of the need to change. Similarly, the school counselor should not directly oppose defensiveness presented by the student. Rather, the school counselor should interpret the presence of resistance as a directive to change approaches. Consistently, the school counselor must maintain the attitude that the student is the primary resource for generating solutions to the current situation. It is not the school counselor's responsibility to find all the answers—and attempting to do so may just cause a student to find fault in each proposed suggestion. Ultimately, the student will be living with the new lifestyle; it only makes sense that the changes are built on the strategies determined by the student.

School counselor: While part of you wants to reduce your partying, another part of you is worried about how your friends will react to such a change (*Develop discrepancy*).

Billy: I don't think I'm an alcoholic or anything. I mean, I've never hurt anybody else or myself, and I've never had any legal trouble or anything like that.

School counselor: I'm not here to "label" you as addict, diagnose any "problem," or convince you to do anything you don't want to do. I'm just here to help you take a look at your current situation and how you'd like things to be. One thing you feel proud about is that you've never hurt anyone else when you've been drinking (*Express empathy*). Tell me more about the things you feel good about in your social life (*Roll with resistance*).

Support self-efficacy. One of the most important guiding principles in the MI approach is the conviction to support self-efficacy. "Perceived self-efficacy refers to beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997, p. 3). Obviously, the belief in one's ability to successfully bring about change is an important precursor to engaging in change. Students who do not believe they are able to go through the process of change successfully are less likely to even attempt change. Thus, a school counselor must consistently support the self-efficacy of students throughout the change process. The following dialogue highlights supporting self-efficacy in the process of change.

Billy: I don't know if I can really follow through with being part of a treatment group. I'm not very good at talking in front of others.

School counselor: You've been very good at sharing your perspective with me. You also mentioned that your friends really seem to trust and respect you. I believe those strengths could help you be very successful in a group.

Following the previously described guiding principles of MI, there are additional strategies that can assist a student with change. Facilitating "change-talk," responding appropriately to resistance, and strengthening the commitment to change are MI strategies that utilize specific counseling techniques to assist students.

Change-talk. Change-talk is dialogue between school counselor and student that is oriented toward the advantages of behavioral change. This dialogue tends to fall into four categories: (a) disadvantages of the status quo, (b) advantages of change, (c) optimism about change, and (d) intention to change (Miller & Rollnick, 2002). To facilitate change-talk a school counselor will want to ask specific, open-ended questions in the subsequent order of the four given categories. Consider how these open-ended questions can be used with the case example.

1. Disadvantages of status quo

School counselor: What worries you about your current situation?

Billy: I was already behind on assignments and now it's worse since I've been suspended. The week stresses me out so much I can only look forward to the weekend, and then I'm so exhausted from partying Friday night that I can't focus on doing any schoolwork Saturday.

School counselor: You're afraid that you are so far behind on assignments that catching up seems impossible. While you enjoy the release of partying Friday night, the consequences are you feel bad Saturday and can't get any homework done.

Billy: Yeah, it's kind of a bad trap I guess. I should cut back on my drinking—at least until I catch up.

The school counselor used an open-ended question to elicit the student's perspective on the disadvantages of the status quo. Then the school counselor carefully paraphrased the disadvantages expressed by the student.

School counselor: Why do you think you need to do something about your partying?

Billy: I guess I'm sick of feeling tired all the time—and it's not just the weekends anymore.

School counselor: In what ways does this concern you?

Billy: Well, I don't want to be like some loser drunk who can't hold down a job.

School counselor: What do you think will happen if you don't change anything?

Billy: I'll probably fail most of my classes and I won't be able to graduate with the rest of my class.

The preceding discussion between student and school counselor illustrates how the example open-ended questions can be used to evoke a discussion of the disadvantages of the status quo. The dialogue presented here is an accelerated example of a discussion that likely needs to be conducted in much greater depth with the student. It is important to note that in the example above, as with discussions in greater depth, the disadvantages of the status quo are those described by the student, not points argued by the school counselor.

2. Advantages of change

School counselor: How would you like things to be different?

Billy: I wish things were going better. I wish I weren't so far behind in school. I wish I wasn't so tired all the time.

School counselor: Describe how school could be better.

Billy: Well, I could be passing all my classes. I could be able to stay alert in class and understand what's going on.

School counselor: Describe how you'd like to be less "tired all the time."

Billy: I'd like it to be easier to get up in the morning and not feel like I'm dragging my body around for hours. I'd like to feel awake and alert, more able to focus and finish homework assignments.

School counselor: What would be the advantages of making some changes in your life?

Billy: I think I would feel much less stressed out if I were caught up in school. I'd feel better in the morning if I weren't out drinking the night before. My Mom would be less worried about me, my Dad might hassle me less. I could graduate high school next year.

3. Optimism about change

School counselor: What makes you think that if you decide to make a change you could do it?

Billy: Well, I'm that not sure I can really. But, I've got to do something. I can't afford to get busted again and I really want to make it through the year and not have to go to summer school to catch up.

School counselor: How confident are you—say on a scale from zero to ten where zero is not at all confident and 10 is extremely confident—regarding this change?

Billy: Probably a five for changing my partying and a four for passing all my classes . . . maybe a 4.5 overall.

School counselor: Why a 4.5 and not a zero?

Billy: Well, I know I need to do something. My mom came down on me pretty hard when I was suspended and I was able to cut back some. I know if I can cut back on drinking I will focus better and catch up in school.

Here, the school counselor has used an open-ended question to explore the student's optimism toward change. To further this understanding, the school counselor asks the student to rate his confidence on a scale of 1 to 10. This is another MI technique (sometimes called a "ruler")

designed to assess the student's confidence and to further elicit change-talk. Notice that the school counselor asked why the student's assessment was not lower (and not the opposite). This encourages the student to express strengths toward change. Asking the student, "Why is it 4.5 and not 10?" would force the student to argue against change. The ruler technique can be used further as described in the following example.

4. Intention to change

School counselor: What would it take for you to go from 4.5 to a 5 or a 6?

Billy: If I had some sort of plan, I mean, if I knew what sort of steps I was going to take . . . and if, if I'd started the steps…then I'd feel more like an 8 or a 9, maybe even a 10 if I'd already started initiating the plan.

School counselor: What do you think you might do?

Billy: Well, I could just stay in weeknights or not drink on weekends, but then I wouldn't know what to do when I go out with friends. . . . I guess I can't really think of any other ways.

Here, the school counselor builds on the ruler technique by asking the student to describe how he might further progression toward change. Moreover, the school counselor is tapping into the student's current change strategies and the student's estimated probability of success for those strategies. In this respect, the school counselor has determined what the student believes is necessary to move toward change and has ascertained that the student lacks constructive strategies for moving toward change.

The case example illustrates some strategies for eliciting change-talk. Equally important is how a school counselor responds to change-talk. Miller and Rollnick (2002) encouraged the use of specific counseling skills as a means of furthering change-talk and enhancing intrinsic motivation. These skills include (a) elaborating change-talk, (b) summarizing change-talk, (c) affirming change-talk, (d) clarifying ambivalence, and (e) clarifying values.

Elaborating change-talk is accomplished when a school counselor encourages a student to expound on statements of change. The school counselor helps the student explore change-talk by using furthering responses such as, "Tell me more about . . . [student's change statement]," "What are some other reasons you might want to make a change?" or "Give me an example of . . ." (Miller & Rollnick, 2002, p. 87). The intent of these directive counseling responses is to help the student to further explore his or her intentions toward change.

Equally important in responding to student statements of change is stating a reflection of student change-talk. This skill can help student clarify ambivalence around change and continue exploration of intentions toward change. Recall the previous school counselor responses in the case example.

School counselor: You'd like to see yourself getting back on track in school and cutting back on your drinking. Right now you are discouraged about not passing your classes and partying keeps you exhausted most of the time.

The school counselor response reflects student change-talk. It is important for school counselors to be aware that reflecting student statements of change can sometimes engender psychological reactants in a student and elicit student statements against change.

School counselor: You'd like to end your pattern of partying and being exhausted the next day.

Billy: Well, going out with friends gives me relief from the stresses of school.

In such cases, it is necessary to use what Miller and Rollnick (2002) referred to as "double-sided reflection" (p. 101). Double-sided reflection can help a school counselor avoid being caught in the position of arguing for change while the student argues against it.

School counselor: You like the stress relief you feel from going out with friends and you hate feeling physically bad the next day after having been out partying with alcohol.

Summarizing change-talk is also another way for school counselors to assist students in exploring their feelings and thoughts about change. "In general, summaries are collections of change statements the person has made: disadvantages of the status quo, reasons for change, optimism about change, and desire to change" (Miller & Rollnick, 2002, p. 90). As with double-sided reflection, when reflecting change-talk, including both sides of ambivalence can be effective in facilitating student movement toward change.

Affirming change-talk is also an important school counselor response to student self-motivational change statements. Selective school counselor responses such as "That sounds like a good idea" and "That's a good point" (Miller & Rollnick, 2002, p. 91) can serve to reinforce a student's commitment to change and facilitate movement through the stages of change.

Clarifying ambivalence involves helping a student to examine each side of the conflict surrounding change. This might mean the school counselor and student evaluate separately the pros and cons for each of the change

alternatives as well as the status quo. It is important that the school counselor and student complete this process for each alternative separately as well as the current behavior/status quo.

Clarifying values is equally important and intrinsically related to clarifying ambivalence. Students must be aware of their personal values in order to evaluate the advantages and disadvantages of change. Helping to discern what is truly important can help a student resolve ambivalence around change. Consider the following discussion.

School counselor: Let's talk about some of the options you have been considering for making changes in your life. We can evaluate the advantages and drawbacks of each. Let's start with your current lifestyle. What are some of the things you like about your current lifestyle?

Billy: Okay, I have a lot of friends. I always have someone to go do something with. And I like to go to parties and getting drunk.

School counselor: You like that you have many people who want to spend time with you. What else?

Billy: I like going to parties and getting drunk.

School counselor: You enjoy how you feel when you're drunk.

Billy: Yes, it feels good. I'm not worried about school or my Dad hassling me. And I'm funny when I'm drunk.

School counselor: So, drinking makes you forget about school and not be troubled by anyone's demands of you. Also, you enjoy being funny and you believe being drunk helps you be funny.

Billy: Well, I can be funny without being drunk, I mean maybe it just helps me feel loose enough to make jokes.

School counselors: Okay, so you value a sense of humor and you believe you can be very funny but you're not always so confident about displaying your sense of humor. What are some of the disadvantages of your current lifestyle?

Billy: Well, I'm tired all the time.

School counselor: Why do you think you're so tired?

Billy: Well, when I'm out late I feel tired and hungover the next day and it's hard for me to focus. Sometimes I get grumpy with my Mom for no reason. Also, I have a hard time understanding things from school and so I fall further behind.

School counselor: So feeling physically good is important to you. You also value your mother. Making progress in school is also important to you.

Billy: Yes, I do value my Mom, in fact that's part of why I want to stay on track toward graduation. Also, it would be nice to have both my Mom and Dad get off my back about school. I wish they could just trust me to take of things on my own.

School counselor: So you value handling things independently as well and you think your parents might give you more control over your life if you made some positive changes.

In the previous discussion, the student and school counselor are exploring some of the pros and cons of the student's current lifestyle. Moreover, they are discerning the student's values and how those values relate to the student's current lifestyle and the potential change(s) therein.

Values are imperative to the change process for students with addictive behaviors. As with other facets of counseling, it is important that school counselors explore with their students the relevancy of their personal values to lifestyle choices. These values need to be explored with an understanding of the student's cultural identity and in consideration of the student's worldview.

Cultural Considerations

It is essential for school counselors to realize that values are embedded in a social and cultural context. Therefore, school counselors need to understand the student's worldview and cultural identity in order to assist the student in exploring his or her values. Kluckhohn and Strodtbeck (1961) proposed a value-orientation model for the conceptualization of cultural values. While empirical evidence in support of this model is mixed (Carter, 1991), it can at least provide a framework for school counselors to use in exploring student values.

For example, some research indicates that African American students may have what Klockhohn and Strodtbeck (1961) defined as a collateral view of social relations (Carter & Helms, 1987). With this awareness and conceptual framework, a school counselor might wish to explore with an African American student his or her social support network, the value system of the student's family/social network, and determine how the student's current and future choices impact the student's social/family relations.

Dealing With Resistance

Some school counselors find the most challenging aspect of counseling students with addictive behaviors is encountering resistance. As mentioned previously, the MI approach takes a somewhat nontraditional view of resistance in the counseling relationship. Rather than interpreting resistance as a student trait that needs to be defeated, MI views resistance as a function of the counseling relationship. More specifically, resistance is in a sense, a reaction to what is happening in the counseling session and a signal to defer

the current tactic in favor of another approach. While this view of resistance is in and of itself a strategy for working with resistance in the process of change, there are additional strategies that a school counselor might employ when encountering resistance: (a) simple reflection, (b) double-sided reflection, (c) amplified reflection, (d) reframing, and (e) agreeing with a twist. These are five techniques posited by MI to diminish resistance and foster progress through the stages of change (Miller & Rollnick, 2002).

Simple reflection. One response to resistance is a reflective listening statement (Miller & Rollnick, 2002). By acknowledging the student's disagreement, disbelief, doubts about change, or differing perception, a school counselor can avoid fostering increased defensiveness:

Billy: Who are you to tell me to stop partying? You've probably never had to put up with the kind of stress I'm dealing with. You've probably never even tried pot.
School counselor: It's hard for you to imagine that I could possibly understand what you're dealing with.

The principles of MI continue to apply when dealing with resistance and giving simple reflection. It is imperative that the school counselor continues to express empathy and to support self-efficacy in subsequent work with the student. Similarly, a school counselor may see an opportunity to deal with resistance and continue to develop discrepancy through double-sided reflection.

Double-sided reflection. Sometimes resistance may manifest itself in the counseling relationship through a student's continued exploration of only the one side of the change argument. In response to this type of resistance, it is helpful to use the previously discussed technique of double-sided reflection. Double-sided reflection is a technique that can assist school counselor and student in exploring both sides of ambivalence (Miller & Rollnick, 2002).

Billy: Yes, I'm going out drinking lot more than I used to, but it's not like I'm getting stoned or jacked up on coke all the time, I mean, I've only been drunk a few times at school activities and no one really sees me as an alcoholic.
School counselor: Part of you is concerned about your increased drinking and another part thinks it's also important to you that people don't view you as an "alcoholic."

When counseling students with addictive behaviors, double-sided reflection might also incorporate the facets of ambivalence that relate to decisions about change.

John: I know it makes sense to cut back on my partying if I'm going to start doing better in school, but I don't think you realize how much stress I'm under, it's like a hammer beating me down all the time!
School counselor: You'd really like to decrease your drinking and you are afraid of how you'll cope without drinking to help you deal with stress.

As with other strategies suggested throughout this chapter, double-sided reflection has potential application for many problematic student behaviors as well as for counseling students struggling with addictive behaviors. Just as student choices and behaviors in school are inherently connected with student addictive behaviors, counseling interventions in one area can be used to assist facilitating change in the other as well.

Amplified reflection. Another potentially effective method for responding to resistance is amplified reflection. "A related and quite useful response is to reflect back what the person has said in an amplified or exaggerated form—to state it in an even more extreme fashion" (Miller & Rollnick, 2002, p. 101). It is important to note that this should be done in a serious, straightforward tone that does not suggest sarcasm or criticism. A negative or sarcastic statement from the school counselor would likely only elicit greater resistance from the student.

Billy: I couldn't give up my partying with friends, I mean, what would they think—that I'm some kind of loser?
School counselor: You can't even imagine not drinking when out with your friends. You couldn't handle their reaction if you quit.

Or

Billy: You make it sound like I'm a raging alcoholic! I don't have a drinking problem!
School counselor: You don't see any negative consequences from your alcohol use—and you resent that I brought it up. In fact, you really see no connection at all between your partying and your problems in school.
Billy: Well, I know I need to take a look at how that stuff is impacting where I want to go . . . I mean, the partying isn't making it any easier to pass my classes.

In each of the two preceding examples, the school counselor used amplified reflection to respond to resistance in the counseling relationship. In the second example, the school counselor responded specifically to exploring the impact of the student's addictive behaviors on his lack of success in school. The school counselor's response utiliz-

ing amplified reflection elicited the student's arguments for exploring the relationship between addictive behaviors and problems in school.

Reframing. Sometimes students express resistance through a self-defeating, problematic, or counterproductive view of a situation. "A persistent use of a false or problematic perceptual frame indicates that the client is 'stuck' and likely to continue unless a change in perception can be engineered" (Gerber, 2003, p. 144). Reframing is the process of helping a student to alter the maladaptive frame into a new perceptual frame. More specifically, reframing in MI may mean helping to generate a more adaptive perception of the process of change.

Billy: I've tried to cut back on going out drinking before, but I always get back into it.
School counselor: You're very persistent. You're not afraid to try again when you aren't successful initially!

Or

Billy: I don't know why I should bother trying to do better in school, I've started out every semester swearing I'll do better and I end up putting off assignments until I'm flunking.
School counselor: You've done a great job noticing some of the mistakes you've made in getting to where you are—now you'll be able to avoid a lot of problems as we go through the process of changing.

Agreeing with a twist. Miller and Rollnick (2002) proposed another technique for rolling with resistance, which they have entitled "agreeing with a twist." This technique involves initially concurring with a student by reflecting their message coupled with a slight twist or modification of resistant momentum. "Agreement with a twist is basically a reflection followed by a reframe" (p. 105).

Billy: You're probably going to tell me I need to do some AA program or something. It wears me out just thinking about it.
School counselor: You're exactly right—if I were to make out a giant "to do" list for you it would probably just prevent you from starting to do anything. It's ironic isn't it—when you're told what you "have to do" it can actually prevent you from doing the very things you want to do.

These aforementioned strategies may provide some useful techniques for counseling students with addictive behaviors. When coupled with the philosophical perspective that resistance is an indicator for a school counselor to change approaches rather than a student's pure rejection of positive change, these techniques can assist school counselors in helping their students avoid the detrimental consequences of addictive behaviors.

Selecting a Treatment Program

Once a student has successfully negotiated the contemplation stage and determined that the negative consequences of the addictive behaviors warrant a behavioral change, a school counselor can be central in helping a student develop an action plan during the preparation stage. In assisting the student with developing an action plan, the process may benefit from the school counselor's developing a treatment plan that considers the unique characteristics of the student and then matching a treatment program with those attributes.

Some evidence suggests that matching student attributes to the specifically selected treatment when selecting treatment programs will increase the likelihood of treatment efficacy (Brown et al., 2002; Mattson, 1994; Project Match, 1997). In the broadest sense, this means considering factors such as student age, gender, severity of substance abuse, level of social support, and financial resources. On another level, school counselors might consider student preferences and cognitive, affective, or behavioral "style" in addition to cultural worldview in helping students to select a treatment approach. For example, a Mexican American student with a strong sense of family and joint decision making might benefit from bringing in his or her family to assist in selecting the treatment plan. Similarly, a school counselor might need to provide an alternate cognitive frame by labeling this step as a "plan for academic and career success" rather than a treatment plan, in order to avoid the stigma some cultures associate with seeking psychological help or therapy.

School counselors also need to consider indigenous treatment plans and/or traditional healers as potentially culturally responsive options for students. Fisher and Harrison (2005) described many such treatment options for groups such as African Americans, including programs such as the *Glide Memorial Methodist Church* in San Francisco, the *Free-N-One* recovery program, the *Nation of Islam* program, and the *African American Survivors Program*.

Using an assessment can also help a school counselor in developing a treatment plan with a student. There are no shortages of assessments to assist school counselors in determining the severity of student substance abuse (the Addiction Research Institute at the University of Texas provides a list of different assessments via their Web site, which is listed at the end of this chapter). School counsel-

ors can use assessments to assist students in determining suitable treatment.

Magura, Schildhaus, Rosenblum, and Gastfriend (2002) discussed using the American Society of Addiction Medicine (ASAM) Patient Placement Criteria in determining the appropriate level of treatment. The criteria outline four levels of care: (a) standard outpatient, (b) intensive outpatient, (c) residential, and (d) hospital. Moreover, these authors suggested using the following variables to determine the appropriate treatment level: acute detoxification and/or withdrawal, biomedical conditions, emotional/behavioral conditions, treatment acceptance/resistance, relapse potential, and recovery environment. Considering these variables can help school counselors in finding appropriate treatment programs and making referrals.

SAMHSA provides a Web site service that locates substance abuse treatment facilities nationally. School counselors can use this service as a starting point in an investigation of available referrals for their area.

Additional Considerations

Geographic location can have an influence on planning for treatment. Rural areas have the same rates of alcoholism and drug abuse yet often lack the same access to health care services (U.S. Department of Health and Human Services, 2007). For this reason, school counselors in rural areas may need to make special arrangements to help students get treatment. This may mean incorporating travel arrangements into the treatment planning process and/or connecting with rural primary care providers in order to secure substance abuse treatment. Consistent with culturally responsive counseling practice, school counselors in rural areas need to search for community sponsored programs and resources that may can be incorporated into the student's treatment plan.

A school counselor may also need to help a student negotiate a balance between treatment and school requirements. This may require a school counselor to advocate on behalf of a student with teachers/administration or assist a student by serving as a liaison between treatment facilities and the school.

It is important to note that in working with a student to determine treatment as part of the preparation stage, the process and outcome are contingent on the continued involvement and engagement of the student. The student is obviously the most important factor in any treatment formula.

Conclusion

What is the status of Billy in the case example? The school counselor has developed discrepancy between Billy's current addictive behaviors and the things Billy would like to accomplish. Billy has moved from precontemplation to contemplation. He is ready to explore further his ambivalence around his use of alcohol, his partying behaviors, and the behaviors he will need to change in order to become more successful in school. As he has already noted several disparaging aspects of his current behaviors, he is already beginning to tip the scale in favor of positive change. Soon he will be ready to explore options for beginning to alter his addictive behaviors and develop a plan of action, as the preparation stage necessitates.

It is imperative that the school counselor and Billy consider all potential implications of his plan of action. It may be useful for the school counselor and Billy to generate a menu of options for various potential plans and then evaluate each for the advantages/disadvantages and the probability of success. As always, the school counselor will continue to foster Billy's sense of self-efficacy by continuing to review the substantial progress he continues to make in improving his lifestyle by changing his addictive behaviors and improving his accomplishments in school.

Understanding the stages of change for behaviors can assist school counselors in working with students struggling with addiction. Knowledge of a student's current stage of change can help a school counselor conceptualize the necessary tasks for the student to continue on the path toward positive change. Moreover, the four guiding principles of MI—express empathy, develop discrepancy, roll with resistance, and support self-efficacy—can provide a solid foundation for counseling students with addictive behaviors. The specific MI counseling techniques introduced in this chapter provide school counselors with a repertoire of tools to help them further positive change in students and avoid the potential pitfalls posed by resistance.

Finally, while the case example demonstrates the stages of change and the use of specific counseling techniques, it is obviously a very simple example. The process of change is often difficult, impaired by frequent pitfalls and setbacks. It is important that school counselors not give up on the process of change, just as they ask students to continue to strive for positive change in their lives. Similarly, realizing the importance of addressing substance abuse by less confrontational means may require a substantial change in practice for individual school counselors and even the profession as a whole.

Accountability and Professional Issues in School Counseling

XLIII
EVALUATING SCHOOL GUIDANCE AND COUNSELING PROGRAMS: Past, Present, and Future

NORMAN C. GYSBERS
University of Missouri–Columbia

Education today is under intense pressure to be accountable for student academic achievement (No Child Left Behind Act, U.S. Department of Education, 2001). All educational programs, including guidance and counseling, are being asked to demonstrate their contributions to overall student success in general and student academic achievement in particular. As a result, it is not surprising to find that guidance and counseling program evaluation is in the forefront of professional discussion and action across the country (Dahir & Stone, 2003; Gysbers & Henderson, 2006; Isaacs, 2003; S. Johnson & Johnson, 2003; Myrick, 2003a).

School counselors, working within the framework of comprehensive guidance and counseling programs, are being asked to demonstrate that their work contributes to student success, particularly student academic achievement. Not only are school counselors being asked to tell what they do, but they are also being asked to demonstrate how what they do makes a difference in the lives of students. They are being asked to be accountable and to be answerable for their work.

Given the current emphasis on evaluation, is this a new phenomenon, or has our profession always been concerned about evaluating the impact of the work of school counselors? What is the profession doing today to respond to the current emphasis on evaluation? What does the future hold for evaluating school guidance and counseling programs? The three sections that follow provide answers to these questions.

The Past: The Evolution of Evaluation

As early as the 1920s, concerns about evaluation began to be raised. Payne (1924) pointed out that it was necessary to evaluate the work being done in guidance:

> What method do we have of checking the results of our guidance? For particular groups was it guidance, misguidance, or merely a contributing experience? We simply must work out some definite method of testing and checking the results of our work. If we do not, some other group will, with possibly disastrous results for our work. (p. 63)

Much of the work on evaluation in the early years focused on establishing standards for judging whether a guidance and counseling program was complete. The need to develop such standards to judge the completeness of a program arose because of the wide array of activities being conducted under the banner of guidance and counseling. Proctor (1930) stated the problem this way:

> One of the great needs in the field of guidance is some fairly objective means of comparing the guidance activities of one secondary school system with that of another. It is only in this manner that we shall ever arrive at an estimate of what constitutes a standard setup for the carrying out of a guidance program. (p. 58)

As work continued on identifying standards to measure what the standard setup for guidance and counseling should be, work was also underway in the 1930s to identify the possible outcomes of guidance and counseling programs. A number of writers, focusing on results, began to identify possible outcomes. For example, Christy, Stewart, and Rosecrance (1930), Hinderman (1930), and Rosecrance (1930) identified the following student outcomes that they thought would result from students' participating in guidance and counseling programs:

- fewer pupils dropping out of school,
- increase in the standard of scholarship,
- better morale in the student body,
- better all-around school life,
- fewer student failures and subject withdrawals,
- young people better informed about the future,
- satisfactory adjustment of graduates to community life and vocation and to a college or university,
- fewer disciplinary cases,
- fewer absences,
- more intelligent selection of subjects, and
- better study habits.

Not only did researchers focus on possible outcomes for guidance and counseling during these early years, but in addition, several of them undertook scientifically based studies to investigate the impact of guidance and counseling on the lives of students. Most notable were the studies conducted by Kefauver and Hand (1941) in the early 1930s and by Rothney and Roens (1950) in the latter part of the 1930s. In both longitudinal studies, these researchers found significant differences in favor of the experimental groups that had received guidance and counseling activities and services. Of particular interest to us today was the finding in the Kefauver and Hand study:

> [S]tudents in the experimental schools typically made slighter greater gains in mean scores on the Stanford Achievement Test than did the students (1) in the corresponding control situations, or (2) those who had been graduated by the two experimental schools prior to the 3-year period during which the study reported in this section of the volume was conducted. (p. 215)

Later, Rothney (1958) conducted the Wisconsin Counseling Study. In it, all 870 sophomores in the high schools in four communities in Wisconsin were placed in either an experimental group or a control group. The experimental groups received an intensive guidance program while the controls did not. On graduation day in June 1951, there were 690 graduates. Three follow-ups took place (a) 6 months after high school graduation, (b) 2.5 years after graduation, and (c) 5 years after graduation in 1956. Of the students who were living (685), 100% participated in the final follow-up. Here are the findings of this landmark study. Students who received counseling:

1. Achieved slightly higher academic records in high school and post–high school education.
2. Indicated more realism about their own strengths and weaknesses at the time they were graduated from high school.
3. Were less dissatisfied with their high school experiences.
4. Had different vocational aspirations.
5. Were more consistent in expression of, entering into, and remaining in their vocational choices, classified by areas.
6. Made more progress in employment during the 5-year period following high school graduation.
7. Were more likely to have gone on to higher education, to remain to graduate, and to plan for continuation of higher education.
8. Were more satisfied with their post–high school education.
9. Expressed greater satisfaction with their status 5 years after high school and were more satisfied in retrospect with their post–high school experiences.
10. Participated in more self-improvement activities after completing high school.
11. Looked back more favorably on the counseling they had obtained. (Rothney, 1958, pp. 479–480)

The 1960s, 1970s, and 1980s witnessed the rapid expansion of guidance and counseling in the schools. Increasing numbers of school counselors were employed, particularly at the elementary level. Interest in evaluation also increased. Numerous articles were written exhorting school counselors to evaluate their work and lamenting the fact that more was not being done (Pine, 1975; Rothney & Farwell, 1960; Wilson & Rotter, 1982). Tamminen and Miller (1968) expressed their concerns about the lack of attention to evaluating the impact of guidance and counseling programs very directly using the words *faith, hope,* and *charity*:

> Faith, hope, and charity have characterized the American attitude toward guidance programs—faith in their effectiveness, hope that they can meet important if not always clearly specified need, and charity in not demanding more evaluative evidence that the faith and hope are justified. (p. 3)

Some school districts, during this time, took on the task of being accountable. School counselors in Mesa, Arizona, for example, expressed a need to focus on results or outcomes.

> Our main objective was, briefly stated, to reduce the size of our "universe" down to manageable size and then—within the parameters of this "new" definition of guidance—be responsible, i.e., *accountable*. We were committed to move toward a model of accountability—based not only upon what counselors did—but rather based on results or outcomes in terms of observable student behaviors. (McKinnon, n.d., p. iii)

Continued expressions of concern about the lack of evaluation of guidance and counseling programs were voiced during the 1990s. For example, Lee and Workman (1992) noted, "Compared to other areas of the profession, school counseling seems to have little empirical evidence to support claims that it has a significant impact on the development of children and adolescents" (p. 15). Gysbers, Hughey, Starr, and Lapan (1992) described the overall evaluation framework that guided Missouri's efforts to evaluate comprehensive school guidance programs. Two of the five questions that guided the evaluation process focused on the measurement of students' mastery of guidance competencies and the possible impact of the program on the climate and goals of the school.

Later in the 1990s, Whitson (1996) outlined a number of approaches to research that could be used in many settings, including school settings. She pointed out that school counselors were encountering increased pressure to be accountable and, hence, needed to be more active in outcome research. Then, Whitson and Sexton (1998) presented a review of school counseling outcome research published between 1988 and 1995. In their opening sentence, they stated, "In this era of accountability, school counselors increasingly are asked to provide information to parents, administrators, and legislators on the effectiveness of school counseling activities" (p. 412).

The Present: Personnel + Program = Results

The emphasis on evaluation that began in the 1920s has continued with renewed vigor in this the first decade of the 21st century. Trevisan and Hubert (2001) reiterated statements made over the past 20 years concerning the importance of program evaluation and of obtaining accountability data regarded student results. Foster, Watson, Meeks, and Young (2002) also reiterated the need for accountability for school counselors and offered the single-subject research design as a way to demonstrate effectiveness. Lapan (2001) stressed the importance of comprehensive programs of guidance and counseling "conceptualized as results-based systems" (p. 289). In his article, he described a framework for guidance program planning and evaluation. And, Hughes and James (2001) noted the importance of using accountability data with site-based management teams and other school personnel.

Given the intense pressure for school counselors, working within the framework of comprehensive guidance and counseling programs, to evaluate their work and to be accountable, what is the current thinking about evaluation? Gysbers and Henderson (2006) answered this question by describing three kinds of evaluation—namely, (1) personnel evaluation, (2) program evaluation, and (3) results evaluation. They used the formula Personnel + Program = Results to describe the relationships of these three types. The American School Counselor Association's (ASCA) *National Model* (2003) also answered this question by identifying three types of evaluation using similar titles: (1) school counselor performance standards (personnel evaluation), (2) program audit (program evaluation), and (3) results reports (results evaluation).

What is involved in these three types of evaluation? Personnel evaluation describes the standards and procedures used to evaluate the work of school counselors. Program evaluation describes the standards and procedures used to determine the degree to which a school district's (school building's) guidance and counseling program is being implemented. Results evaluation focuses on the impact that a school district's (building) guidance and counseling program and its activities and services are having on students, the district (building), and the community.

Each type of evaluation is important. Equally important, however, is how they relate to and interact with each other. School counselors must be doing the work of the comprehensive school guidance and counseling program full-time. At the same time, the program must be fully implemented. When school counselors are engaged full-time in the program, and the program is in place and functioning the way it should, it then becomes possible to conduct results evaluation to ascertain the contributions that the program maybe making to overall student success in general and student academic achievement specifically.

Personnel Evaluation

In the past, school counselors were evaluated using teacher evaluation procedures and forms. Teacher procedures and forms were used because the work of school counselors was not well defined and would often vary building by building across school districts. The traditional organizers for guidance and counseling in the schools, the position and services models, did not provide sufficient structure to clearly establish well-defined roles for school counselors.

When comprehensive school guidance and counseling program frameworks evolved in the 1970s and 1980s,

however, the bases for clearly identifying and evaluating the work of school counselors emerged. It became possible to establish the duties of school counselors district wide within the framework of a comprehensive program using the language of the program. Once this happened, performance standards and criteria to evaluate the work of school counselors followed (ASCA, 2003; Henderson & Gysbers, 1998; Missouri Department of Elementary and Secondary Education, 2000).

Today, performance standards and criteria are being used with increasing frequency to supervise and evaluate school counselors. Performance standards are acknowledged measures of comparison used to make judgments about the scope of the work of school counselors within a comprehensive program. Once a sufficient number of performance standards have been identified, criteria are prepared that specify the important aspects of the standards. Enough criteria are needed to provide evaluators with confidence that each standard has been fulfilled.

Table 43.1 presents 6 standards and 15 criteria for performance-based professional school counselor evaluation developed by the Missouri Department of Elementary and Secondary Education (2000). Standards 1 through 4 were derived directly from the comprehensive guidance program framework used by the state of Missouri. Standards 5 and 6 focus on school counselors' communication and interaction within schools as well as school counselors' professional responsibilities. In Table 43.2, example descriptors are provided for the first 2 criteria. Each of the remaining 13 criteria also has descriptors that more fully explain the operational details of the criteria.

In Missouri, school counselor evaluation is both formative and summative. Ongoing professional development and supervision procedures using the standards and criteria constitute the formative part of the evaluation. Various forms used to conduct the formative part of the evaluation are available in the *Guidelines for Performance-Based Professional School Counselor Evaluation* document (Missouri Department of Elementary and Secondary Education, 2000; this document can be obtained at http://www.dese.mo.gov/divteachqual/profdev/Counselorscorrected2.pdf).

The summative part involves an evaluator's collecting and documenting the work of school counselors to be used in school counselor evaluation. Table 43.3 presents a data collection form using 2 example criteria from the standards and criteria found in Table 43.1. The information from the form in Table 43.3 is used to make judgments concerning school counselor performance for each of the 15 criteria based on a 3-point rating scale of "meets expectations," "progressing toward meeting expectation," and "does not meet expectations." See Table 43.4 for an example of this type of rating for the first 2 criteria.

Program Evaluation

What is program evaluation? How do we determine which activities and services and what organizational structure constitutes a program? What forms and procedures are used to conduct program evaluation?

Program evaluation is a procedure used to determine the degree to which a school district's comprehensive guidance and counseling program is in place and fully functioning. It can also be used as a self-study procedure to ascertain how a current program measures up before beginning a revision of the program. In other situations, such as in the state of Utah, program evaluation is conducted for purposes of funding (Utah State Office of Education, 2003).

"What constitutes a standard set-up for the carrying out of a guidance program" (Proctor, 1930, p. 58)? This question, asked many years ago, identifies a major issue in program evaluation today. Due to the work of Gysbers and Henderson (2006), Myrick (2003b), S. Johnson, C. Johnson, and Downs (2006), and the ASCA (2003), we know what activities, services, and organizational structure constitute a complete comprehensive guidance and counseling program.

Based on this knowledge it is possible to construct the forms and procedures used in program evaluation. This work begins with the development of standards and criteria. Just as was the case in personnel evaluation, enough standards are required to fully document that a complete comprehensive school guidance and counseling program is in place and functioning the way it should. Criteria are then needed for each standard to adequately specify the important aspects of each standard. It is important to understand that the standards and criteria must be derived directly from a comprehensive guidance and counseling program model to ensure that a complete program has been captured by the standards and criteria. The standards and criteria must match the desired program framework.

Once the standards and criteria have been chosen that fully represent a comprehensive guidance and counseling program, a scale is created for each of the criteria that can range from 1 to 5, 6, or 7 points. Sometimes a scoring guide that describes what an evaluator would look for at each point is provided. A scoring guide can also include examples of evidence evaluators would expect to find along with the documentation required to show the degree to which the standards and criteria have been met.

There are numerous examples of program evaluation forms available. States such as Missouri and Utah have developed forms based on their state models for comprehensive guidance and counseling programs. The ASCA (2003) included an example in their *National Model.* Care must be taken, however, in using state or national standards and criteria and the forms. Unless a local distinct has

Table 43.1 Standards and Criteria for Performance-Based Professional School Counselor Evaluation

Standard 1:	The professional school counselor implements the Guidance Curriculum Component through the use of effective instructional skills and the careful planning of structured group sessions for all students.
Criterion 1:	The professional school counselor teaches guidance units effectively.
Criterion 2:	The professional school counselor encourages staff involvement to ensure the effective implementation of the guidance curriculum.
Standard 2:	The professional school counselor implements the Individual Planning Component by guiding individuals and groups of students and their parents through the development of educational and career plans.
Criterion 3:	The professional school counselor, in collaboration with parents, helps students establish goals and develop and use planning skills.
Criterion 4:	The professional school counselor demonstrates accurate and appropriate interpretation of assessment data and the presentation of relevant, unbiased information.
Standard 3:	The professional school counselor implements the Responsive Services Component through the effective use of individual and small group counseling, consultation, and referral skills.
Criterion 5:	The professional school counselor counsels individual students and small groups of students with identified needs/concerns.
Criterion 6:	The professional school counselor consults effectively with parents, teachers, administrators and other relevant individuals.
Criterion 7:	The professional school counselor implements an effective referral process in collaboration with parents, administrators, teachers and other school personnel.
Standard 4:	The professional school counselor implements the System Support Component through effective guidance program management and support for other educational programs.
Criterion 8:	The professional school counselor provides a comprehensive and balanced guidance program in collaboration with school staff.
Criterion 9:	The professional school counselor provides support for other school programs.
Standard 5:	The professional school counselor uses professional communication and interaction with the school community.
Criterion 10:	The professional school counselor demonstrates positive interpersonal relations with students.
Criterion 11:	The professional school counselor demonstrates interpersonal relations with educational staff.
Criterion 12:	The professional school counselor demonstrates positive, interpersonal relations with parents/patrons.
Standard 6:	The professional school counselor fulfills professional responsibilities.
Criterion 13:	The professional school counselor demonstrates a commitment to ongoing professional growth.
Criterion 14:	The professional school counselor possesses professional and responsible work habits.
Criterion 15:	The professional school counselor follows the profession's ethical and legal standards and guidelines, as well as promotes cultural diversity and inclusivity in school policy and interpersonal relationships.

Table 43.2 Professional School Counselor Evaluation Criteria with Descriptors: An Example

Note: The descriptors provided are simply examples of student and counselor behaviors that may be used to document criteria. The descriptors provided are not intended to be an inclusive list. The observation and/or documentation of each criterion will vary based on the context.

Standard 1: The professional school counselor implements the Guidance Curriculum Component through the use of effective instructional skills and the careful planning of structured group sessions for all students.

Criterion 1: The professional school counselor teaches guidance units effectively.

The professional school counselor:

1. Organizes units for student mastery based on student needs.
2. Uses effective instructional strategies.
3. Establishes an environment conducive for student learning through the use of effective classroom management techniques.
4. Other. ...

Criterion 2: The professional school counselor encourages staff involvement to ensure the effective implementation of the guidance curriculum.

The professional school counselor:

1. Collaborates with or assists teachers in developing and/or teaching guidance units effectively.
2. Serves as a resource regarding guidance materials appropriate to the guidance units being taught.
3. Provides in-service training for teachers on guidance-related subject matter and guidance instruction methodology.
4. Other. ...

adopted a state or national model completely, some modifications may be needed in the forms to reflect the nature and structure of the program the district has developed.

When and how often a district conducts program evaluation depends on the purposes to be achieved. For self-study purposes, the ASCA (2003) recommended that program evaluation be conducted when a program is being designed and yearly thereafter. The state of Utah uses program evaluation to determine whether a school district has met the standards for program organization and implementation in order to receive state funding (Utah State Office of Education, 2003). Whether program evaluation is done yearly or periodically, this type of evaluation provides the opportunity to determine if the written district program is the actual implemented district program. The results of program evaluation reveal where progress has been made or progress is lacking in overall comprehensive guidance and counseling program implementation.

Results Evaluation

Results evaluation is the process used to answer the question, What impact do comprehensive guidance and counseling programs (activities and services) have on students' success, particularly on students' academic achievement? Outcomes typically addressed in results evaluation include attendance, discipline referrals, grade point averages, achievement test scores, and classroom behaviors. Results evaluation focuses on how outcomes such as these may change due to students' participation in the district's comprehensive guidance and counseling program.

It is recommended that school counselors develop and carry out a results-based evaluation plan as a part of the

Table 43.3 Comprehensive Data Collection Form: Two Example Criteria

The Comprehensive Data Collection Form is used by both the administrator/supervisor and professional school counselor to summarize the documentation of each performance criterion over the course of the evaluation cycle. It should be maintained in the administrator's/supervisor's office with a copy in the PSC's portfolio. It should be reviewed periodically to determine the professional school counselor's progress. This document will provide an overview of the professional school counselor's performance to be used during the Evaluation Report. It serves as a composite of all the data collected. All data should be copied and discussed with the professional school counselor prior to entering it into the file.

overall implementation of their district's comprehensive guidance and counseling programs. The outcomes to be addressed in the plan should come from the district's comprehensive school improvement plan, mission statement, and/or strategic plan. These documents contain outcomes chosen as important for a district to achieve. Since comprehensive guidance and counseling programs can make substantial contributions to the achievement of such outcomes, they can become the outcomes that are focused on in a results evaluation plan.

A results evaluation plan can focus on specific guidance and counseling activities or services chosen because they address specific outcomes identified in the district's comprehensive improvement plan. If this approach is chosen, then the plan needs to include the specific outcomes desired, the activities or services to be used that can address the desired outcomes, how the activities or services will be provided and by whom, the evaluation design to be used, how the data will be collected and analyzed, and what kind of report (e.g., PowerPoint presentation) will be prepared and to whom it will be presented.

As an illustration of a study that looked at the outcomes of a specific guidance and counseling activity, Brigman and Campbell (2003) tested a guidance curriculum titled "Student Success Skills" that focused on student cognitive, social, and self-management skills using a quasi-experimental, pre/post test design. School counselors conducted group sessions for students in grades 5, 6, 8, and 9. The treatment group scored significantly higher than control group on the reading and math scores of the Florida Comprehensive Assessment Test.

A results evaluation plan can also focus more broadly on the impact of an entire district guidance and counseling programs for K–12 or a specific grade grouping such as elementary, middle school, or high school districtwide or statewide. The same procedures identified previously would be used. To illustrate this approach, two statewide studies are presented—one conducted in Missouri and one in the state of Washington.

Lapan, Gysbers, and Petroski (2001) found that when 4,868 middle school classroom teachers in Missouri in 184 small, medium, and large sized middle schools rated guidance programs in their schools as more fully implemented, 22,601 seventh graders in these schools reported that they earned higher grades, school was more relevant for them, they had positive relationships with teachers, they were

more satisfied with their education, and they felt safer in school. Sink and Stroh (2003), in a comparison of elementary students (grades 3 and 4) enrolled for several years in well-established comprehensive school counseling program schools with students enrolled in schools without such programs, found that students enrolled in schools with the well-established programs had significantly higher academic achievement test scores on the Iowa Tests of Basic Skills—Form M and the Washington Assessment of Student Learning.

In designing a results evaluation plan, several types of data can be used. Process data, the first type, describe what guidance and counseling activities and services were provided, when, and for whom. Process data provide evidence that guidance and counseling activities and services were actually provided. Perception data, the second type, tell us what students, parents, teachers, administrators, or others think about or feel about the activities and services and the work of school counselors. Outcome data (results data), the third type, are the actual behaviors of students as measured by attendance rates, discipline referral rates, grade point averages, and achievement test scores. All three types of data are useful in ascertaining the impact of comprehensive guidance and counseling programs on student behavior.

A major phase of developing and carrying out a results evaluation plan is the collection of the data. When will the results data be gathered and be whom? C. D. Johnson (1991) recommended that long-range, intermediate, and immediate data need to be considered. Long-range results data focus on how comprehensive guidance and counseling programs or the activities and services involved affect students after they leave school. Often collecting these kinds of data involves using a follow-up study design. Intermediate results focus on what impact the program has on students some period after they have participated in program activities and services while immediate results describe the impact of specific activities and services soon after they have been conducted.

The data collection schedule for results evaluation should be established prior to the initial date of the results evaluation period and should specify

- the guidance activity or service for which the data will be collected;
- the instrument(s) to be used;
- the group(s) or individuals from whom data will be collected;
- the time when data will be collected (pretest, posttest, end of year, and so forth) in relation to the process schedule; and
- the person(s) to be responsible for data collection.

The evaluation design chosen, including the types of comparisons to be made, will dictate most of the decisions relevant to the data collection schedule. Evaluation data collected for groups to make pretest/posttest comparisons or experimental group/control group comparisons need to conform closely to the time required to complete the chosen guidance and counseling activity. Pretest or baseline data need to be collected prior to the initiation of the guidance and counseling activities, and posttest data need to be collected at a specified time after completion of the guidance and counseling activities being evaluated (immediate results). Some designs also may require the collection of data at specified periods during the guidance and counseling activity period or as follow-up sometime after the completion of the guidance and counseling activity (intermediate or long-range results). All such data need to be collected on a predetermined schedule so that all persons involved in the results evaluation process can make plans and carry out the data collection in accordance with the design.

"School counselors do not have to be skilled statisticians to meaningfully analyze data" (ASCA, 2003, p. 51). This is true, but school counselors do need to master some basic statistical concepts to successfully analyze and interpret results data. In addition, school counselors need to know how to disaggregate data appropriately, enter data on spreadsheets such as Excel, do appropriate analyses, and develop graphs and charts displaying the data in understandable ways.

Disaggregating data is an important step in data analysis because it allows us to see if there are any students who are not doing as well as others. The ASCA (2003) suggested that the common fields for disaggregating data are as follows:

- gender,
- ethnicity,
- socioeconomic status (free and reduced lunch),
- vocational (multiperiod vocational program track),
- language spoken at home,
- special education,
- grade level, and
- teacher(s). (p. 50)

An important tool for results data analysis is a spreadsheet such as Excel. Spreadsheets allow us to enter results data and conduct various statistical procedures as appropriate. In addition, various charts and graphs can be created to show relationships of results data to possible outcomes such as state achievement test scores and external tests such as the SAT or ACT.

Some types of evaluation information are not easily adaptable to spreadsheet analyses, however, and may in fact be more meaningful when analyzed by counselors

and their staff. For example, subjective counselor reports of guidance and counseling activities or certain types of student behaviors may lose meaning if quantified. These subjective analyses may be critical in the interpretation of other outcome data. In addition, small samples of activities or students may not warrant the use of computer analysis and thus will need to be handled manually. In such cases, precautions should be taken to reduce human error to a minimum by establishing checks and rechecks.

Finally, a results evaluation plan needs to emphasize how results data will be used. One use of such data is to demonstrate the contributions school counselors make to the goals of education as presented in the district's comprehensive school improvement plan. The second is how the data are used to enhance the district's current comprehensive guidance and counseling program. Results evaluation data serve to both prove and improve the program.

The Future: Bright and Full of Promise

It is well documented that evaluation has been part of professional discussion and action since the 1920s (Gysbers, 2004). Each decade of the 20th century saw repeated exhortations to conduct evaluation studies, particularly ones that focused on results. These decades also saw substantial efforts to actually conduct evaluation studies, including experimental control studies, to determine the impact of specific guidance and counseling activities and services as well as the overall impact of complete programs.

Given the past and present emphasis on evaluation, on being accountable, what about the future? I believe that the future is bright and full of promise because the profession is finally at a point of agreement that guidance and counseling is a program, not simply a set of services or a position. There is also general agreement about a common language that defines and describes the basic framework used to structure, organize, and sequence guidance and counseling activities and services K–12. In addition, there is general agreement that the content (student knowledge and skills) of guidance and counseling programs to be delivered to students can be organized around the three domains of academic, career, and personal/social.

Why is common language important for guidance and counseling programs? Common language enables school counselors, administrators, teachers, and parents or guardians to "coordinate their work and multiply the power of their intellects" (American College Testing Program, 1998, p. 9). Common language for guidance and counseling programs also allows these "individuals to communicate and replicate" (p. 9) guidance and counseling program activities. In addition, common language for guidance and counseling programs provides the basis for program, personnel, and results evaluation across a school district, grades K–12.

School counselors also have available at their fingertips technology that could not have been imagined years ago. Personal computers and software packages are available that can organize, analyze, and report results in various formats. This technology enables school counselors to take charge of results evaluation once they have mastered the basics of these software packages. The advances in hardware and software, that are sure to occur in the future, point to even more possibilities for evaluation.

Unfortunately, even with all of the knowledge and technology available today, some school counselors still see evaluation as a threat. What they need to do is rid their minds of the phobia of evaluation, of the persistent fear of evaluation that often leads to a compelling desire to avoid it. What will be required is a mindset that evaluation is simply a part of the guidance and counseling work that school counselors do in schools every day. It is a way that their work can be improved and its effectiveness demonstrated. It is important to begin each school year, semester, month, week, and day by being results oriented.

Finally, it is important to remember that evaluation talk is not enough. It is time for action. It is time for school counselors at all levels to accept the challenge of evaluation. The past has much to offer us concerning this challenge and how to address it. Let us use the wisdom of the past to address the challenge of evaluation today and into the future.

XLIV
RESEARCH IN AND ON SCHOOL COUNSELING

BRYAN S. K. KIM
University of Hawaii at Hilo
SAUL G. ALAMILLA
University of California, Santa Barbara

As is true for other areas in the field of education, there have been increasing pressures on the school counseling profession to be more accountable to the public concerning their relevance and effectiveness in helping students to be successful in the schools. The most recent example of this press of accountability has been the passing of the No Child Left Behind Act of 2001 (U.S. Department of Education, 2002) legislation. This law mandates school systems to be more accountable for the academic successes and failures of their students. An important consequence of this law, and the more general current trend on accountability, is that there now are even greater pressures on the school counseling profession to demonstrate its effectiveness in meeting students' emotional and social developmental needs and helping them to attain academic success.

Another source of this demand for accountability on the school counseling profession has been the increasing racial and ethnic diversification of our school systems. The past 4 decades in the United States have witnessed a dramatic increase in the number of individuals from diverse cultural backgrounds, mainly due to high immigration and birth rates among non-European American persons. Currently, African Americans and Latino Americans each represent 13% of the total U.S. population, with Asian Americans and American Indians representing 4% and 1%, respectively (U.S. Census Bureau, 2002). By the year 2050, it has been estimated that the number of racial and ethnic minority individuals will be nearly 50% of the U.S. population (U.S. Census Bureau). Already in California, Hawaii, and New Mexico, the number of "minority" persons represents over 50% of these states' populations, whereas Texas's minority population constitutes 48% (Hobbs & Stoops, 2002). An important implication of these data is that there will be a dramatic increase in the enrollment of students from diverse backgrounds in the school systems and that school personnel will be facing significant challenges posed by this increasing diversity. In particular, school counselors will be faced with meeting the unique needs of various cultural groups, while continuing to maintain their effectiveness with students from European American backgrounds. In addition, these demographic changes pose an important challenge for the school counseling profession to demonstrate and document their relevance and effectiveness in meeting the needs of the increasingly diverse student body.

One way in which the school counseling profession can demonstrate the important roles it plays in the lives of students is through research in and on school counseling. Research in and on school counseling can generate empirical evidence that can be used to demonstrate that school counselors are an integral part of the educational mission of the school systems. It can show that the practice of school counseling can have important and positive effects on the lives of students and the school community in general. It can show that the varied roles played by counselors in the schools help students cope with the many developmental challenges they face within the emotional, social, and academic arenas of their lives. Hence, research in and on counseling can be an important component of demonstrating accountability for the profession in meeting the needs of the student population.

Given this background, the purpose of this chapter is to describe and critique the current state of research in and on school counseling. First, we will present a conceptual framework that can be used to evaluate various facets of validity of research findings. This framework will be illustrated using a hypothetical counseling research study. Second, using this framework, we will critique the current state of school counseling research by examining two representative areas: (a) effectiveness of comprehen-

sive school counseling programs and (b) efficacy of roles played by school counselors. We elected to choose these two areas of research because they seem most proximal to addressing the demand for accountability facing the school counseling profession. We should note that, although there may be some overlap between our review of comprehensive school counseling programs and that other chapters in this *Handbook* (e.g., Schmidt, Chapter 1, this volume), our focus will be on methodological strengths and limitations, in an attempt to help illustrate the general state of current research in and on school counseling. Third, we will examine the literature on the extent to which school counseling professionals are involved in research endeavors and the amount of attention devoted to empirical work in major school counseling publication outlets. Finally, we will offer directions for future research in and on school counseling.

A Conceptual Framework to Evaluate the Validity of Research Findings in School Counseling

The basic purpose of a research study is to isolate and assess the constructs of interest, to identify the relationship between the constructs, and simultaneously, to eliminate alternative hypotheses for the observed relationship (Heppner, Kivlighan, & Wampold, 1999). In this process, the concept of MAXMINCON is an important one to keep in mind (Kerlinger, 1986). MAXMINCON refers to *max*imizing the explained variance (i.e., controlled variation that is determined by the research design), *min*imizing the error variance (i.e., random error or noise), and *con*trolling irrelevant variables (e.g., using a covariate). When the explained variance between constructs of interest is at its greatest, the error variance is at its minimal, and the control variables have been fully and accurately identified, a study's results have the greatest chance of showing a true significant effect or relationship. However, a number of threats can jeopardize the validity of the study's findings. These threats are categorized into five types: (a) statistical conclusion validity, (b) internal validity, (c) construct validity of putative causes and effects, (d) external validity, and (e) hypothesis validity.

To illustrate these five threats, we would like to present a hypothetical research study that school counseling researchers might conduct. Imagine that you are a school counselor at a middle school who is interested in conducting an experimental study on the effects of a group intervention designed to enhance multicultural sensitivity among middle school students. Your idea for this research stemmed from your readings of the multicultural literature that suggested the importance of instilling awareness and knowledge about cultural diversity to adolescents. The literature suggested that this could lead individuals to function more effectively in our increasingly diverse society. After gaining approval to conduct research with human subjects from the school's administration, you randomly select 100 seventh graders from the entire seventh-grade class as participants in your study. Fortunately, you are able to gain informed consents from the parents of all 100 students and informed assents from all of these students to participate in your study.

To begin the study, you randomly assign 50 students to the experimental condition, and these students are again randomly divided into 5 groups of 10 students each. Each of these groups is given ten 50-minute group counseling sessions in which students learn about cultural diversity and to become more multiculturally aware, based on a manual you have developed. The groups meet 2 times each week and are facilitated by five different professional counselors whom you have trained. For the other 50 students, you also randomly divide them into 5 groups of 10 students each. Rather than receiving the treatment, they are shown a 50-minute *National Geographic* presentation about the animal kingdom across 10 meetings, held 2 times per week. Similar to the experimental condition, this control condition is facilitated by the five counselors who introduce and show the videotape presentation; however, no discussion is held after the showing to minimize contact between the counselors and students. After 5 weeks, you have the participants complete measures of multicultural self-efficacy to examine the differences between the two conditions on these scores.

Now, we turn our attention back to the five threats to validity and use this research example to illustrate these threats. Statistical conclusion validity refers to the extent to which researchers can be confident that the observed relationship between the variables of interest is accurate (Heppner et al., 1999). The threats that exist for this type of validity are related to making either Type I error (rejecting the null hypothesis when the null hypothesis is true) or Type II error (accepting the null hypothesis when the null hypothesis is not true). An example of a Type I error is finding a false significant relationship because of conducting numerous statistical tests. Conducting a large number of tests increases the likelihood of finding a significant relationship due to pure chance (this is also called fishing and error rate problem; Heppner et al.). In the preceding example, if you had administered several measures of multicultural competence and compared these scores separately to identify differences between the experimental and control condition without controlling for Type I error, you could be falsely concluding that the experimental condition had a positive effect because the significant differences could be due to chance. To avoid this situation, you might reduce

the alpha level (e.g., Bonferroni correction) to conduct a more conservative statistical test. Alternatively, you might combine the scores of all of the measures into one score and simply conduct one comparison test (e.g., t-test).

In terms of Type II errors, a research study could lack adequate statistical sensitivity and not detect an effect or relationship when there is a true effect or relationship. One way this could occur is by having an insufficient sample size. Another way is to use instruments that have inadequate reliability (i.e., increased measurement error) that lead to a lack of statistical power. In the study just described, you could avoid a Type II error by conducting an a priori power analysis to determine the exact number of participants one might need given the alpha level for the statistical test(s), expected effect size (i.e., the size of the difference between the experimental and control groups), type of statistical test used (e.g., t-test, correlation, multivariate tests), and power of the statistical test (i.e., the degree to which you are willing to accept a Type II error—generally this is 20%, which leads to a power of .80). Often, researchers use a "rule of thumb"—for example, 20 participants per condition for a group counseling intervention. But this is a very rough and imprecise way of determining an optimal sample size, and it could lead to an inadequate number of participants. Regarding the issue of reliability, one could examine the internal consistency (e.g., Cronbach's alpha) of the scores from the measures used to ensure that the scores are relatively free of measurement error.

On a related note, an important consideration in avoiding Type I and Type II errors is to use the most appropriate statistical tests to analyze the data. In the previous example, five counselors each saw 10 students in both the experimental and control conditions. This situation creates dependence on each data point (i.e., outcome score) between the counselor and the student in each group. In other words, the participant scores are nested within the counselor to whom they were assigned. One way to address such a situation is to use tests such as hierarchical linear modeling that can account for the variance on the outcome score that is attributed to the counselor–student pairing. Without addressing this problem, the researcher would have made incorrect conclusions. In general, to avoid statistical analysis problems, we encourage school counseling researchers to consult with statistical books and/or consultants before engaging in data analyses.

Internal validity refers to the extent to which researchers can be confident that the causal relationship specified in the design of the study is indeed true. Essentially, internal validity of a study is increased when alternative and competing explanatory hypotheses are eliminated, thereby increasing the likelihood that the observed relationship with the dependent variables is indeed caused by the independent variables. Internal validity of a study is high when the independent variable(s) is manipulated, the participants are randomly assigned to comparison groups (typically treatment and control), and the research procedures (e.g., assessment, implementation of intervention) are given at the same time (Heppner et al., 1999). In studies involving experimental and control groups, there is a greater internal validity when both groups are equivalent on all characteristics except the independent variable that is being manipulated; this is usually accomplished via random assignment. When these conditions are not met, threats to internal validity are present.

Heppner et al. (1999) described a number of possible threats to internal validity. For example, when there is no manipulation of a variable in a study, the threat to internal validity is high, and a causal relationship cannot be made even when a statistically significant relationship is detected between the treatment experience and outcome variables of interest. An example of this type of a design is the one-group, pre/post test design in which there is no comparison group. Also, another design with high threat to internal validity is the correlational design in which there is no manipulation of the variables of interest. For these types of studies, only a relational conclusion can be made (e.g., a positive correlation exists between self-esteem and academic achievement). Even if a design employs a comparison group, when the participants are not randomly assigned into the two groups, threat to internal validity is present because a statistically significant difference between the two groups may be attributed to factors other than the intended treatment (i.e., pretreatment differences such as developmental level or achievement level). Also, when treatments are not given at the same time, threat to internal validity may be present because the treatment group at Time 1 may also receive unintended forms of treatment from external factors, which may not be present at Time 2 when the other group is offered the comparison condition. An internal validity problem also would exist if the group at Time 2 matured more quickly than the treatment group at Time 1; that is, it is not clear whether the observed difference between the two groups was due to the differential maturation rates or the treatments themselves.

Heppner et al. (1999) pointed out that the design that is least prone to threats to internal validity is the posttest only experimental control group design (see the following illustration).

R	X	O_1
R		O_2

In this design, "R" refers to random assignment of participants to the two groups. "O_1" refers to posttest assessment

in the first group, and "O_2" refers to the posttest assessment in the second group. "X" refers to the presence of treatment of interest; hence, treatment is given to the first group but not to the second group and the independent variable has two levels, treatment versus no treatment. This design meets the following conditions necessary for high internal validity: random assignment, manipulation of independent variable (i.e., treatment vs. no treatment), and the implementation of research procedures (e.g., assessment) at the same time.

In the preceding example, the study is designed to be free of threats to internal validity because you have randomly assigned participants into experimental and control groups. You also have a clear manipulation of your variable of interest (i.e., multicultural sensitivity training vs. no training), and the group counseling sessions are held at the same time. However, as you can imagine, this study is ideal in nature and such a design may not be possible in a typical school setting. In such a situation, a researcher might need to sacrifice some of the tenets of internal validity such as settling for nonrandom assignment and using existing classrooms to conduct the study. Here, the researcher would assign one classroom to the experimental condition and another to the control condition. In such a design, known as a quasi-experimental design, a major threat that is present, as previously mentioned, is that it is not clear whether the observed differences on the outcome scores are due to preexisting differences between the classes, for example, having a multicultural-focused curriculum in one class and another curriculum in the other class, or your intervention. To mitigate such a difference, it is important for researchers to ensure that if existing groups are going to be used over random assignment, the two groups are equal in as many aspects as possible (e.g., age, sex ratio, academic level, socioeconomic level, curriculum, and teachers' teaching and personality styles). For a study in which the experimental and control conditions cannot be given simultaneously, researchers should try to ensure that there is no major event, particularly related to multicultural sensitivity in our example, which is present for one group but not for another group. The presence of such an event is known as history, and this is one of the most serious threats to validity when the interventions are not administered simultaneously.

Construct validity of putative causes and effects refers to the extent to which the measured constructs accurately represent the constructs of interest (Heppner et al., 1999). A confound exists when there is ambiguity between the measured constructs and the constructs of interest. In essence, confound refers to having an alternative construct(s) embedded in the instruments that are designed to measure the construct of interest. Threats to construct validity usually occur when there is either an underrepresentation of the construct itself or an overrepresentation of construct irrelevancies. According to Heppner et al. (1999), specific threats to the construct validity of putative causes and effects might occur when (a) the construct is not fully explicated and the operationalization of the construct includes only a limited amount of construct representation, (b) the construct is assessed using only one measure and thus limiting the measurement of the full range of the construct, (c) the construct is measured using only one method such as self-reports, (d) subjects guess the experimental hypothesis and respond according to their guesses, (e) subjects feel anxious about the evaluation and do not respond accurately, and (f) the experimenter gives subtle messages that may affect the responses by the subjects.

In the example study presented previously, the group counselors used a manual that you developed based on extant literature on how multicultural sensitivity can be achieved. In designing this intervention, you have carefully included a comprehensive array of components that fully represents the constructs of multicultural sensitivity. In addition, you have carefully chosen instruments that assess self-reported, multicultural self-efficacy to determine the effects of your treatment program accurately. On the other hand, if such a measure was not taken and the group counseling intervention did not fully represent multicultural sensitivity, there may be a problem with construct validity. Also, if in administering the program, the five counselors in the treatment condition unknowingly deviated from the manual and perhaps were much nicer to their group members than to the students who watched *National Geographic* shows, the level of "niceness" of the counselors could become a confound, which is a serious threat to construct validity. Furthermore, another area of a potential construct validity problem is that the research study presented previously depended solely on self-reports of participants to assess their multicultural self-efficacy. In this regard, a stronger study would be to add a third-party observation (e.g., teacher or parent ratings) as a supplemental measure of students' multicultural self-efficacy. This method would strengthen the construct validity of the outcomes of group counseling.

External validity refers to the extent to which the results of a study are generalizable to other people, settings, and time (Heppner et al., 1999). A threat to external validity exists when there is an interaction between selection and treatment such that the treatment is effective on only the population on whom the treatment was tested. Given the increasing diversification of our school systems, as previously described, this threat is an important one to consider with respect to school counseling becoming more relevant and effective with non-European American clients. Another threat to external validity occurs when there is an interaction between setting and treatment such

that the treatment is effective in only the setting in which the treatment was tested. Given the vastness of the United States, it is important to consider whether a treatment that was shown to be effective in one part of the country will be effective in another distant part. A final threat to external validity involves an interaction between history and treatment such that the treatment is effective only during the time that the treatment was tested. Hence, it is important to examine the current efficacy of a treatment method that was found to be effective during a previous time. To illustrate, in the preceding example study, you randomly selected the participants from all seventh graders in the school, which allowed the study to have a strong external validity in terms of its findings to the rest of the seventh-grade population in the school. However, one must be cautioned that the generalizability of the findings may not hold up in other schools, especially those schools with students whose characteristics are very different from the students in your school. In such a situation, it would be important for the study to be replicated in schools at other geographical locations and at other times to examine the extent to which the results are generalizable.

Finally, Wampold, Davis, and Good (1990) proposed hypothesis validity as an additional factor to consider when examining the rigor of a study. Wampold et al. described that threats to hypothesis validity can be present when there is an inconsequential hypothesis, such that the hypothesis of interest is not based on theory and does not result in convergence of theory (i.e., supporting the theory of interest while refuting alternative theories). Other threats to hypothesis validity involve having an ambiguous hypothesis such that the hypothesis is not stated in clear and falsifiable terms, having a lack of congruence between the experimental hypothesis and statistical hypothesis, and having a diffusion of statistical hypothesis (e.g., using an omnibus hypothesis when a more specific hypothesis should be used). In the study presented previously, the null hypothesis that was tested was that there would be no difference between the experimental and control conditions on the self-reported scores of multicultural self-efficacy, the alternative hypothesis being that there is a significant difference on multicultural self-efficacy. Because this hypothesis was based on extant theoretical literature on multicultural counseling, one can be confident that the study has hypothesis validity. However, if the hypothesis was not based on any theory—for example, that there would be a positive effect on students' career aspirations—there would be a concern about the validity of this hypothesis.

To summarize, a useful framework to critique the quality of research includes five domains: statistical conclusion validity, internal validity, construct validity of putative causes and effects, external validity, and hypothesis validity. These threats were illustrated using a hypothetical school counseling research study. Now, we turn our attention to existing research on school counseling. These studies will be described in the following section and evaluated based on this conceptual framework.

A Review and Critique of Current Research

Research on Comprehensive School Counseling Programs

In reviewing the research on comprehensive school counseling programs, it is helpful to begin with review articles; we found three of these types of articles. In one of the earlier reviews, Pine (1975) reviewed the extant research and found that studies on school counseling programs tended to examine a wide range of outcome variables including academic achievement, peer relations, personal adjustment, school attendance, school adjustment, self-concept, self-esteem, reduction of inappropriate behaviors, and setting realistic goals. In terms of the research methods that were employed, Pine listed the following: (a) experimental design (posttest only without control, pre/post test without control, and pre/post test with control), (b) descriptive method, (c) case study method, and (d) second person method. Pine concluded that there is evidence to support the effectiveness of school counseling programs but recommended that researchers use more formal methods for evaluating school counseling programs.

In the early 1990s, Borders and Drury (1992) conducted a review of articles on counseling programs that had been published between the 1960s and 1990 in peer-reviewed journals (e.g., *Journal of Counseling and Development*, *The School Counselor*, *Elementary School Guidance and Counseling*, and *Measurement and Evaluation in Counseling Development*). Based on their review, Borders and Drury identified the common characteristics, principles, scope, and nature of comprehensive school counseling programs. They found that there are four principles that characterize these programs: (1) they are substantive and systematic, with clearly delineated and measurable goals, objectives, and interventions; (2) they are fully integrated and integral to the general educational mission of the program (e.g., they work in tandem with and in service to other educational activities in the schools); (3) they possess a holistic and/or developmental theoretical focus (e.g., cognitive, social, and psychological factors that foster and advance the academic, personal, social, and career development of all students); (4) they are equally accessible to all students; and (5) they are guided by clearly written policies that

uphold the confidentiality and protect the privacy of students and other participants (e.g., teachers and families).

In terms of effectiveness, Borders and Drury (1992) reported that (a) there was support for individual and small group counseling interventions (e.g., improved student self-esteem and academic achievement); (b) there was mixed support among and within students for classroom guidance interventions (e.g., one study reviewed revealed significant effects on kindergarten and first-grade but not on third-grade student attendance rates); and (c) there was support for consultation service interventions by showing a positive relationship between the intervention and student behavior, academic achievement, and self-concept.

However, Borders and Drury (1992) did not critique the research methodology of the articles under review, and hence, it is not known the extent to which these findings were based on rigorous and externally valid designs.

More recently, Gysbers (2004) reviewed the literature on school counseling programs that had been published between 1920 and 2003. Based on a sampling of empirical studies published during this time, Gysbers pointed out that these studies addressed two basic issues: "evaluating the impact of specific guidance and counseling activities and services and evaluating the impact of total programs of guidance and counseling" (p. 8). Gysbers also noted that the research designs used ranged from longitudinal to between or within group comparisons. Gysbers found that the results of these studies were generally supportive of vocational guidance and school counseling endeavors, with positive impacts on students' perceptions of the quality of their school and counseling experiences, grades, educational outlook, higher educational opportunities, and/or overall adjustment in and outside of the school environment.

While all three of these review articles are helpful in gaining a sense of the kinds of research work that currently exists on the effectiveness of comprehensive school counseling programs, they do not provide the full picture. In particular, each review article represented a different level of attention to the research rigor of the studies that were reviewed and none of them critiqued the studies in terms of the five types of validity threats. Hence, we would like to offer more detailed reviews of research studies examining the effectiveness of comprehensive school counseling programs with a particular focus on the design issues. This review is followed by a critique of the methodologies using the threats to the five validities as an evaluative framework.

In our search of the school counseling research literature, we identified only five published studies on comprehensive school counseling programs. Lavoritano and Segal (1992) evaluated the effectiveness of Remedial Education and Diagnostic Services (READS), a program that provides psychological and educational testing, counseling, and remedial education services by school counselors. The participants in the program were 152 elementary students from varied ethnic backgrounds and from 20 different schools who were referred to the program. In addition, 74 students were not referred to the program and, hence, did not receive the interventions; they were used as a comparison group. The dependent variables were participants' self-rated competency in six domains: (1) scholastic competence, (2) social acceptance, (3) athletic competence, (4) physical appearance, (5) behavioral conduct, and (6) general self-worth. The authors also investigated whether the participants' self-esteem as measured by the Self-Perception Profile for Children (SPCC; Harter, 1985) had higher scores after the intervention. In their preliminary analysis, the authors found that the students in the intervention group (i.e., students who were referred to the program) were significantly different in several characteristics: They were more likely to be males, they tended to come from single parent homes, they had a greater likelihood of having been retained a grade, they tended to be underachieving, and they tended to score low on the pretest measures on all six domains. In terms of the main research question with respect to the effects of the READS program, the authors conducted paired-samples *t*-tests on the pre/post test scores from the intervention group and found that their scores increased significantly on scholastic competence and decreased significantly on behavioral conduct. No differences were observed between the intervention and comparison group in several one-way analyses of covariance with the differing demographic characteristics as covariates.

Lapan, Gysbers, and Sun (1997) and Lapan, Gysbers, and Petroski (2001) examined the impact of the Missouri Comprehensive Guidance Programs (MCGP) programs among middle and high school students across the state of Missouri during a 7- to 10-year period. Lapan and colleagues (1997) noted that between 1985 and 1997 over 2,200 school counselors and administrators from more than 400 school districts in the state of Missouri had received training in the implementation and management of the MCGP and that over 97% of the state's school counselors were in the process of implementing MCGP. The MCGP is designed to help students with career planning and exploration, personal development (e.g., knowledge of self and of others), and educational and vocational development needs.

Lapan et al. (1997) examined the effects of MCGP on high school students' perceptions of academic achievement and campus climate. The data were obtained from the Missouri School Improvement Program (MSIP) database, which contained information from 22,964 high school students, 236 schools, and 434 school counselors from Missouri. The student outcome variables were assessed using the Secondary

Student Questionnaire (SSQ) that contained student-rated, single-item measures of their current grades, their perceptions of how well their educations were preparing them for the future, and how much they liked school. In addition, a 5-item measure was used to assess students' perception of school climate. Furthermore, counselors were assessed using a 32-item instrument on the degree to which the MCGP was being implemented in their schools. The data were analyzed using hierarchical linear modeling, which allows for the controlling of higher level variations such as differences between schools and school districts. The results indicated that schools with more fully implemented MCGP had students who reported having higher grades; better preparation for their futures, particularly in terms of their career goals; and positive school climate. In addition, positive effects of the program were maintained when differences between schools vis-à-vis enrollment size, student socioeconomic status, and percentage of minority students in the school were controlled.

Lapan et al. (2001) conducted a similar study but with a sample consisting of seventh-grade students and with a different set of outcome variables. Specifically, these researchers examined the impact of the MCGP on students' (a) perceptions of school safety, (b) satisfaction with their education, (c) perceptions of their grades, (d) perceptions of their relationships with their teachers, and (e) perceptions of the importance and relevance of their education to their futures. Again, using hierarchical linear modeling, the authors analyzed data from 22,601 seventh graders and 4,868 teachers from 184 schools and found that, while controlling for school variations on socioeconomic status and enrollment size, when counselors more fully implemented the MCGP (i.e., spent more time in classrooms; assisted students with personal, educational, and career issues; consulted with parents, teachers, and administrative staff when they engaged in individual and group counseling with students; and made appropriate referrals), students reported feeling safer in school, having better relationships with their teachers, having higher grades, being more satisfied with the educational experiences, perceiving their education experiences to be more relevant to their futures, and having a better quality of life. Interestingly, the authors also found that girls reported earning higher grades than boys did and European American students reported having higher grades than minority students did.

In another study examining a comprehensive school counseling program, Brigman and Campbell (2003) studied the effects of the Student Success Skills Program (SSS) on academic success and related behaviors among elementary, middle, and high school students. According to the authors, the SSS is designed to enhance the cognitive, social, and self-management skills that are related to academic success, and it is administered by counselors through classroom guidance and group counseling formats. In the study, the authors used a pre/post test experimental design in which participants in the SSS groups were compared with a control group from other schools with matching geographic location, race, and socioeconomic status. To participate in the SSS groups, 180 students were randomly selected from three elementary, one middle, and two high schools. These participants consisted of fifth, sixth, eighth, and ninth graders who scored between the 25th and 50th percentile on the Florida Comprehensive Assessment Test (FCAT) in reading. For the comparison group, data from the same number of students in the same grade levels with similar test scores were selected from nonparticipating schools. The results showed that participants in the SSS groups scored significantly higher on the FCAT reading and math scores than the students in the comparison groups.

Sink and Stroh (2003) examined whether elementary schools that have a well-established comprehensive school counseling program are enhancing student academic achievement more than schools without such a program. The authors randomly selected 150 public elementary schools in the state of Washington of various sizes and from various socioeconomic strata and collected data on 20,131 students in the third and fourth grades. Based on a multivariate analysis of covariance with a Bonferroni correction, Sink and Stroh found that, while controlling for length of enrollment and gender among students, students scored higher on measures of academic achievement (Iowa Tests of Basic Skills—Form M and the Washington Assessment of Student Learning) when a comprehensive school counseling program was implemented in their schools. Furthermore, increased academic achievement was observed especially among students from low socioeconomic status when their schools had a program in place.

As a whole, the results of these studies lend empirical support to the effectiveness of comprehensive school counseling programs. However, such findings are not without methodological limitations. Although many of these studies appear to have high levels of statistical conclusion and external validities given the large and representative sample sizes and the use of sophisticated data analytic strategies (HLM, MANCOVA with Bonferroni correction), one of the studies (Lavoritano & Segal, 1992) conducted numerous statistical tests without controlling for an inflated Type I error rate. In addition, some of the studies did not have comparison groups to examine the true effects of the school counseling programs. Hence, it is unclear whether the positive effects were indeed caused by the programs, which leads to internal validity concerns. Also, there are concerns about hypothesis and construct validity of the findings. In most of the studies, the authors noted that the observed effect sizes were relatively small. This raises

questions about the extent to which the constructs used to assess the effectiveness of school counseling programs are adequate and if the most common choices of constructs meet the demands of accountability. It also raises the question of whether the effect sizes would have been larger if different outcome measures were used. In Lapan et al. (1997), for instance, student outcomes were assessed using single item measures, and hence, their psychometric adequacy cannot be known. Perhaps the use of more well-established measures of academic and social achievement might have led to larger effect sizes, thereby further strengthening the importance of the outcomes. Moreover, many of the measures used were self-reports, and as such, there was a general lack of objective achievement measures. For example, one of the outcome variables in Lapan et al. was student-reported grades. It could be speculated that the findings might have been strengthened if the actual grades of students were used instead. In addition to using well-established and objective outcome data, alternative methods of assessing student outcomes could have strengthened the studies. For example, Curcio, Mathai, and Roberts (2003) described the helpfulness of using the following types of evaluation tools in their evaluation work: (a) documents (e.g., minutes from counselor monthly meetings and counselor daily activity logs), (b) interviews with school counselors and principals, and (c) focus group discussions with parents, students, and teachers. However, despite all of these limitations in the current literature, it is also important to mention that the overall findings still provide valuable and important information vis-à-vis effectiveness.

We should note that the American School Counselor Association (ASCA; 2003) recently published *The ASCA National Model: A Framework for School Counseling Programs*, a document describing a model for developing and implementing comprehensive school counseling programs. This document offers a model of a comprehensive school guidance and counseling program based on four elements: (1) foundation, (2) delivery System, (3) management systems, and (4) accountability. The foundation element specifies that a guidance and counseling program should be based on a coherent philosophy and mission statement to guide the creation of the program that is related to the ASCA national standards and competencies. The delivery system component describes the mode in which the program is offered, including guidance workshops, individual services, responsive services, and support to systems. The management systems element details the relationship among the roles of school counselors, administrators, and an advisory council in developing, implementing, and evaluating the program. Finally, accountability, the fourth element, describes the importance of assessing whether and to what extent the program has made a positive difference in the lives of students. In proposing this model, the ASCA described the benefits to a variety of constituents including students, parents, teachers, administrators, education boards and departments, school counselors, counselor educators, and communities. While this model is promising, it should be noted that its validity with respect to applicability must also be examined. For example, future research is needed to examine the extent to which the model has been employed by school systems and the degree to which the model was useful in running effective programs.

Research on School Counselor Roles and Duties

In addition to examining the effectiveness of comprehensive school counseling programs in order to study the current state of research in and on school counseling, it is helpful to examine the research that has been done to investigate the efficacy of counselor roles and duties. In defining counselor roles and duties, Myrick (1993) proposed that the roles and duties could be categorized as either direct or indirect services. Myrick described direct services as including individual and group counseling and guidance activities. Indirect services include consultation, coordination (e.g., orchestrating guidance services through special events), and peer facilitation (e.g., "training" of peer counselors). On the other hand, Gysbers and Henderson (1994) proposed a four-category schema describing school counselor roles and duties. This schema include the following roles and duties: (a) guidance curriculum, (b) individual planning, (c) responsive services, and (d) system support. The implementation of a guidance curriculum refers to classroom or group activities designed for all students. Individual planning activities include assessing and advising students regarding their personal, educational, and career goals. Responsive services include preventive or remediation measures via individual, small group, and crisis counseling, and providing referrals and consultation services when and where appropriate. Finally, system support refers to conducting outcome research, professional and staff development, and supervision of school personnel.

Although there appears to be some clarity in terms of what counselor roles and duties ought to be, there has been tension between counselors and administrators about what roles and duties counselors must realistically assume in the school setting (Burnham & Jackson, 2000; Fitch, Newby, Ballestero, & Marshall, 2001). Some administrators believe that counselors should assist with administrative duties such as courses scheduling, coordinating or administering achievement tests, and disciplining students. In a survey of future school administrators, Fitch et al. found that 57% of the respondents rated record keeping, a role

ASCA deemed inappropriate for counselors, as a significant role for school counselors. Also, Burnham and Jackson, in a survey of counselors, found that no less than 65% of the participants reported having engaged in nonguidance or noncounselor related activities. According to ASCA (2003), activities that are appropriate for school counselors include counseling, consulting, academic and career guidance, interpretation of tests, and prevention programs. In light of this tension between some school administrators and counselors, it is imperative that the accountability efforts also focus on evaluating the efficacy of conventional school counselor roles and duties. Hence, in this section, we will examine the current research literature on school counselor roles and duties.

Unfortunately, however, our search of the research literature on counselor roles and duties led to only two articles. Fitch and Marshall (2004) examined the roles and duties of school counselors in terms of enhancing student academic success. The authors studied and compared the activities of school counselors at high- and low-achieving schools to determine if there was a relationship between school performance category and the perceived importance of different counseling duties and time spent on the duties. Participants were school counselors across 62 elementary, middle, and high schools in Kentucky. The participants completed a survey containing a list of 11 roles and duties that were based on the Kentucky School Counseling Standards (Education Professional Standards Board, 1996). The roles and duties were program management, curriculum implementation, counseling, consultation, coordination, assessment, maintenance of professional standards, leadership functions, professional development, advocacy work, and other related work (Fitch & Marshall); these activities are similar to those of ASCA standards. For each of these roles and duties, participants were asked to rate their perceptions of the importance and the amount of time spent on each role or duty. In addition, the participants also completed information on their schools' academic performance on the California Test of Basic Skills, which was used to classify each school as either high or low achieving.

The results indicated that for the ratings of importance of each role or duty, there were no significant differences between high- and low-achieving schools, except for the advocacy role; interestingly, participants in the low-achieving schools rated the advocacy role as more important than did counselors in the high-achieving schools (Fitch & Marshall, 2004). With respect to hours spent on each of the roles and duties, participants in high-achieving schools reported spending more time on program management, assessment, coordination activities, and adherence to professional standards (i.e., aligning their programs to prescribed models or standards) than counselors in low-achieving schools did. The authors also found that, similar to Burnham and Jackson's (2000) findings, counselors in both high- and low-achieving schools reported engaging in clerical activities more than in any other activity except for counseling activities (Fitch & Marshall, 2004). Despite these findings, however, Fitch and Marshall's findings also have some important limitations. The results may not be generalizable given that it was gathered from a convenience sample and in one state, namely, Kentucky. In addition, the study lacked any information about the students in each school. Information such as socioeconomic status and race/ethnicity could help to explain the findings and, at a minimum, should have been kept statistically constant between high- and low-achieving schools. This information also could have revealed the extent to which the findings are generalizable to other schools.

In a study that examined counselor roles and duties beyond those of the conventional direct service provider (e.g., individual and group counselor), Field and Baker (2004) explored nine high school counselors' views on the role of an advocate using a qualitative design. Field and Baker defined advocacy as the following:

> an approach to school counseling in which the counselor goes beyond the tradition verbal 'give and take,' based on theoretical premises and techniques. A school counselor advocates on behalf of an individual student, a student group, or about a student issue; incorporates multicultural competence; provides meaningful information and additional helping resources; and lends support, including appropriate interventions, beyond the four walls on an office. (p. 57)

The participants were divided into two groups and interviewed using a semistructured format. The analysis of the responses revealed the following themes: (a) advocacy required additional or extraordinary interventions, consisted of several interventions, and was focused exclusively on the student; (b) advocacy meant that counselors would support one another in their advocacy roles as well as support their profession; (c) advocacy constituted or was perceived as a belief system or structure, which predated professional training; (d) advocacy consisted of flexible and reflexive behaviors, which were guided by realistic expectations; (e) consistency in demonstrating advocacy beliefs and behaviors was viewed as essential by the counselors; (f) the counselors received positive feedback from students with respect to their advocacy work; (g) support from administrators was also expressed by the counselors; and (h) work overloads prevented counselors from implementing advocacy interventions or engaging in advocacy roles. While these findings are interesting, there are obvious limitations to these results. The limitations include the relatively small

number of participants, data collection in groups that could be affected by social influence dynamics, and data analysis by two persons. Nonetheless, it should be pointed out that this is one of the few studies examining school counselors' implementation of the advocacy role.

While the findings from these two studies are useful, they do not offer a comprehensive view of the current research literature on the efficacy of counselor roles and duties. Hence, we further examined the school counseling literature in the area of counseling interventions. Although reviews of counseling intervention research are presented in the other chapters of this *Handbook,* particularly in Section VI, and they do not necessarily, directly bear on the efficacy of counselor roles and duties, we hoped that this examination would indirectly inform us on the type of counseling tasks that might be engaged in by counselors. We reasoned that counselor roles and duties could be shaped by the interventions they implement in the schools. This effort led us to a relatively recently published article that reviewed the intervention research literature in school counseling.

Whiston and Sexton (1998) reviewed research articles on school counseling interventions that were published between 1988 and 1995. They selected articles that (a) described activities or interventions performed by school counselors, (b) involved K–12 students or parents of school-aged children, and (c) assessed and described the outcome results of the intervention. These criteria led to the identification of 50 empirical studies. To organize these articles, the authors used the four-category schema of Gysbers and Henderson (1994) that was described previously. Based on this model, Whiston and Sexton classified 12 studies under the implementation of guidance curriculum category, 10 studies under the individual planning category, 25 studies under the responsive services category, and 3 studies under the system support category. The authors found that a majority of these studies were quantitative in nature (n = 43), while the remaining used qualitative, evaluative, or follow-up designs. Among the quantitative studies, 31 used descriptive field designs, 11 used experimental field designs, and 1 used an experimental laboratory design. The 12 studies with experimental designs had at least one control group, which suggests a high level of internal validity. However, the remaining 31 descriptive designs were not amenable to any causality conclusions. Also, Whiston and Sexton pointed out that treatment integrity was not documented in 42 of the 50 studies, which raises serious concerns about construct validity of the treatment variable. The authors also mentioned that only 2 of the 50 studies used random sampling, which suggests possible threats to external validity. Furthermore, the authors reported that the majority of quantitative studies did not use statistical tests to analyze the data, thereby raising concerns about the statistical conclusion validity. Based on these findings, Whiston and Sexton concluded, "a broad range of activities school counselors perform often result in positive changes for students . . . however, our conclusions are slightly more tentative due to our evaluations of the methodological limitations" (p. 422).

In summary, our review of the research literature on counselor roles and duties led to only two studies. Although the findings supported the efficacy of the various roles that school counselors play, they are not without methodological limitations. Also, although Whiston and Sexton's (1998) review article showed positive outcomes when counselors implemented the described counseling interventions within their varied roles as described by Gysbers and Henderson (1994), the findings are only indirectly related to the efficacy of counselor roles and duties, and they are limited by methodological concerns. Hence, the lack of available research on school counseling roles and duties poses a significant dilemma in terms of addressing the accountability press. Specifically, while the pressures have increased for the school counseling profession, there appears to be very limited research that can serve as evidence for the efficacy in the various counseling roles that school counselors play. To explore this issue further, we now turn our attention to the issue of the availability of researchers who are conducting school counseling research.

Availability of Researchers Who Are Conducting Research in and on School Counseling

Given the relative paucity of research on efficacy of counselor roles and duties and on comprehensive school counseling programs, it is helpful to examine the extent to which school counseling research is being conducted and to which the findings are published in school counseling journals. Bauman (2004) conducted a survey of 763 randomly selected ASCA school counselors from all 50 states and Puerto Rico. The survey contained 26 items that assessed counselors' views and activities concerning research and school counselors (Bauman). The results of the survey revealed the following: 78.1% of school counselors surveyed disagreed or strongly disagreed with the statement, "I am expected to conduct research as part of my job as a school counselor," whereas only 11.3% agreed or strongly agreed with this statement. Doctoral-degree-holding school counselors were more confident in their research abilities than were non-doctoral-degree-holding school counselors. The former group of school counselors also had more interests in collaborating with university researchers on research endeavors.

In terms of school counselors learning from research findings, Bauman's (2004) results showed that the publica-

tion most widely read by the respondents was the *ASCA School Counselor*, a magazine that publishes mainly practice-focused articles. Only 36% of the school counselors surveyed read the more research-focused *Professional School Counseling* or *Journal of Counseling and Development*. In short, the status quo of research in and on school counseling might be best illustrated by the following observations:

> a participant noted that many school counselors do not value what research can do for their program, and suggested that a lack of emphasis on research on [*sic*] graduate training programs might account for this . . . [whereas another] individual indicated that while her masters' degree program had prepared her well to conduct research, such endeavors [were] not valued by her workplace. (Bauman, 2004, p. 146)

In terms of journal space for articles on school counseling research, Bauman et al. (2002) examined the amount of pages devoted to reporting research findings in and on school counseling. The results indicated that only 25% of the first four volumes of the *Professional School Counseling* journal were devoted to empirical articles and only 19% and 28% of these studies primarily or marginally, respectively, were authored by school district affiliates. Furthermore, 22% of the school counselors surveyed were not keeping abreast of new research findings. Consistent with these results, Whiston and Sexton (1998) lamented about the relative lack of published research in their review of intervention articles. They noted, "[That] only 50 studies were published from 1988 through 1995 is somewhat disappointing" (p. 422).

In summary, it appears that master's level school counselors have little interest or confidence in conducting research. School counselors appear more interested in reading practice-oriented journals than research-oriented ones. Furthermore, research journals tend to devote relatively little space for empirical articles, which makes it more difficult for school counselors to share their research results with other professionals. Although these findings may seem disappointing, it is not surprising given that most school counselor training programs are geared toward practice (vs. research), and there is not a great deal of emphasis on research and publication (for suggestions concerning changes in the training sequence of school counselors to address this concern, see Steward, Neil, & Diemer, Chapter 2, this volume). Nonetheless, the findings raise serious concerns about whether the school counseling profession is well positioned to respond to the challenges of accountability needs. As Whiston and Sexton (1998) noted, "[If] school counseling activities are going to have a substantial empirical base then there needs to be increased interest in researching those activities" (pp. 422–423). They further noted, "We believe that school counselors, counselor educators or researchers, and leaders in professional organizations, such as the American Counseling Association (ACA) and the American School Counselor Association, should work together to increase the amount of outcome research in school counseling" (p. 425).

Implications for Future Research

Based on the findings from this review, several suggestions for future research can be offered. First, in future research studies, it is important to attend to the methodological issues cited previously. Given the many threats to validity present in the current school counseling literature, it is imperative that researchers make strong efforts to design studies that address the five types of validity threats. As previously described, the empirical literatures on the effectiveness of comprehensive school counseling programs and the efficacy of counselor roles and duties have several threats that limit the strength of their findings. Although there are no perfect studies (e.g., Bubble Hypothesis; Gelso, 1979), a concerted effort to enhance the rigor of research investigations in school counseling can go a long way toward strengthening the empirical knowledge base of the field and of the profession.

Second, given that most school counselors do not seem to be conducting research (and perhaps are not expected to), school counselor educators may need to engage in a greater level of research on school counseling. The productivity expectations for school counselor educators, as university faculty members, typically include some level of research publication. Given the current paucity of research in school counseling, particularly as it relates to efficacy of counselor roles and duties, it is imperative that faculty members engage in more research and publication. To this end, greater efforts should be made by ASCA and ACA to lobby departments of counselor education to increase the time and resources allotted for research activities and reduce other duties such as teaching and service. In addition, ASCA and ACA should lobby the Council for Accreditation of Counseling and Related Educational Programs (CACREP), the accreditation agency of many counselor education departments, to increase their standards regarding faculty research productivity.

Third, aside from the work of university faculty members, school counselors can be encouraged to engage in greater amount of research activities, at least in collaboration with counselor educators. Given that the pressures to be accountable to the public largely stems from school administrators, having school counselors conduct research

and show evidence of program effectiveness and role efficacy to their school administrators may be one of the most effective means to meet the accountability press. In cases where significant outcomes are observed, the findings can be shared with other school counselors through various publication outlets. An added benefit of publishing such findings is that it can bring a positive light to the school in general (and even the school district) and to the school administrators in particular to further demonstrate their positive efforts to meet the academic and social needs of their students. To this end, we agree with the point made by Romano and Kachgal (2004) that having a greater level of research collaboration between school counselors and administrators and the university-based counseling researchers could lead to very fruitful results in addressing the accountability demands.

Several authors have proposed alternative methods in which school counselors can engage in more research endeavors. We strongly agree with this idea. Although the conceptual framework presented previously offers ways in which researchers can evaluate their work and strive to conduct more rigorous and valid studies, we realize that there are many limitations within the school setting that restrict the extent to which school counseling researchers have control over how research is conducted. For example, given the limited amount of material resources and time, it may be very difficult for school counselors to conduct true experimental studies in the schools. In recognition of this situation, we strongly believe that it may be just as fruitful if school counselors begin to engage in any and all types of research activities, regardless of how small the scope or limited the rigor of the activity might seem. We feel that doing so may lead to greater momentum for school counselors who then might eventually be able to establish a more rigorous and comprehensive research program in their schools. Collectively, such research activities also could lead to evidence-based practice that is based on methodological diversity, rather than just on experimental designs. To encourage this effort, what follows is a description of research designs representing methodological diversity.

One method is known as action research. Pine (1981) described action research as a descriptive investigation consisting of the following activities: (a) documentation (e.g., collecting, generating, organizing, and synthesizing information); (b) retrospection to accurately account for and reflect the actualities of school counseling effectiveness; and (c) case studies that may provide useful data for more in depth examination of the phenomena of interest.

Pine (1981) pointed out that these are activities that school counselors can carry out as part of their day-to-day professional duties, and that the findings can offer valuable information.

In another variation, Gillies (1993) described action research as "the application of the scientific method of fact-finding and experimentation to practical problems requiring action solutions" (p. 69). According to Gillies, counselors must ask, prior to the initiation of action research, the following queries: (a) what is the problem to be investigated, (b) what was the genesis of the problem, (c) what are the potential repercussions of overlooking the problem, (d) what is the desired outcome, and (e) how can this outcome or goal be attained/obtained?

Based on the consideration of these issues, one of four action research approaches could be chosen: (a) diagnostic action research, (b) participant action research, (c) empirical action research, or (d) experimental action research. According to Gillies (1993), diagnostic action research is appropriate for mundane issues and consists of identifying the problem, assessing causality, and considering and implementing solutions. In contrast, participant action research involves additional sources of information (e.g., teachers and parents) and consists of identifying concerns, defining the problem, inquiring about the need for additional information, collecting and analyzing data, brainstorming solutions, and collaboratively making and implementing suggestions to resolve the problem. The third approach is the empirical action research and this is a more formal research approach than the previously mentioned approaches. It is appropriate for examining the effects of counselor interventions using observational record keeping. Finally, experimental action research utilizes a control and experimental group as well as pre/post test measures. This method is most similar to the published research studies that have been previously described and is appropriate for contributing to theoretical advancement.

Another method is qualitative research. According to Heppner et al. (1999), "Qualitative research involves understanding the complexity of people's lives by examining individual perspectives in context" (p. 235). This method is based on the idea that there is no universal truth that is to be found, as in quantitative research, but that truth is subjective to each individual and that each person creates his or her ideas of the world that are shaped by the social, cultural, economic, and political forces in the environment. The most common method of data collection in qualitative research is through open-ended interviews where the researchers ask questions to participants regarding the issue at hand. The resultant responses are then analyzed for themes that may be similar to or different from the responses of other individuals. In school counseling research, a possible application of qualitative research is to ask the consumers of counseling about the specific benefits of counseling services. If school counselors could ask these questions to all of their clients and document their responses, they could begin to build a database of

information about how people are benefiting from the counseling services.

A third method utilizes the single subject design. Citing the lack of outcome research on school counseling, Foster, Watson, Meeks, and Young (2002) discussed the benefits, as well as the limitations, of the single subject research design. Variations of the single subject design consisted of the following: (a) the A-B design, which is analogous to the pre/post test design but also includes a follow-up component; however, such a design does not rule out confounds, but is appropriate for assessing interventions aimed at acting out behavior; (b) the A-B-A-B design, which addresses the confound limitation of the former design; (c) the multiple baseline design, which is essentially a series of A-B designs; however, this design may be applied to the same individual when assessing varied behaviors, the same individual across different settings, and the same behavior with different individuals; and (d) the changing criterion design, which is another extension of the A-B design; however, in this case, as the criterion changes, the intervention also changes (i.e., design would be appropriate in behavioral interventions). Foster et al. argued that this type of design would address the challenges and critiques of the field as well as the concerns that many school counselors have regarding conducting research, namely, a lack of knowledge of research methodology or confidence in conducting research.

In general, these methods offer alternative ways for school counselors to conduct research activities. Although they are not without methodological limitations, we hope that these strategies will offer more attractive and doable options for school counselors interested in investigating scholarly problems in their school settings.

Finally, there is a need to increase the publication outlets for school counseling research. Currently, there is only one journal specifically devoted to school counseling, *Professional School Counseling* (*PSC*), and this outlet may not offer sufficient page space to meet the empirical accountability press. It should be added that *The School Counselor* and *Elementary School Guidance and Counseling* are no longer in existence, as they were combined to form the *PSC*. Although other journals have been mentioned in this chapter, such as the *Journal of Counseling and Development*, *PSC* is a counseling profession-wide journal that covers research work beyond school counseling. Perhaps efforts can be made to add an increased number of pages to *PSC* and consider other forms of publication such as an electronic journal. An electronic journal can have the same level of rigor in reviewing submitted manuscripts, but it is not bound by the high cost of printing that is associated with paper journals. In addition, the ASCA and the ACA might consider publishing the proceedings that focus on school counselor effectiveness from their annual meetings. This type of publication outlet might be less intimidating especially for beginning scholars and may lead to increased attendance at the conferences.

Conclusion

To conclude, we would like to quote Gysbers (2004), who stated,

> Today the issue of accountability is in the forefront of professional dialogue. . . . Not only are school counselors being asked to tell what they do, they also are being asked to demonstrate how what they do makes a difference in the lives of students. (p. 1)

We cannot agree more with his assessment. Hence, toward this end, we have reviewed the current research literature on school counseling and found several shortcomings, mainly related to methodological issues and the small quantity of research work. We hope that this chapter has offered useful information regarding the present status of research in and on school counseling, areas of strengths and shortcomings, and possible directions for future work.

XLV
THE ESSENTIAL ROLE OF SCHOOL–COMMUNITY PARTNERSHIPS IN SCHOOL COUNSELING

MARY E. WALSH AND JILLIAN DePAUL
Boston College

One of the essential roles of school counselors is to "provide proactive leadership, which engages all stakeholders in the delivery of activities and services to help students achieve success in school" (American School Counselor Association [ASCA], 2003). Best practices call for school counselors, as school leaders who are often responsible for the coordination of resources and services that assist students, to be academically successful, to play a critical role in the development and implementation of school–community partnerships. Over the last decade, school–community partnerships have increased dramatically in the nation's school districts, reflecting an awareness of students' needs for support beyond classroom instruction.

However, throughout most of the 20th century, schools worked in relative isolation from the surrounding community. The high fences and walls that separated the school from the streets and roads of the neighborhood stood as a visible reminder of the inward focus of American schools. In the last quarter of the century, Parent Teacher Associations (PTAs), and health care providers (e.g., physicians and dentists) gradually assumed clearly defined, though narrow, roles in the community's schools. More recently, as schools began to reach out to their communities more broadly, they connected not only to families, but also to businesses, community social services and health agencies, libraries, universities, and more recently youth development organizations and family support centers. These connections between schools and local community institutions have resulted in many positive opportunities for students to participate in a range of supports for learning and healthy development.

Researchers have identified comprehensive school–community partnerships as one of the primary characteristics of effective schools. Partnerships with businesses, universities, and service learning centers are typically the direct responsibility of the school principals. The work of school counselors is most closely aligned with community agency partnerships that offer supports for student learning and healthy development. School counselors can and do play key roles in forming these collaborations (Fitch & Marshall, 2004; McWhirter, McWhirter, McWhirter, & McWhirter, 1998; Wohlstetter & Smyer, 1994). Leaders in the field of school counseling have recognized that school–community partnerships are critical to comprehensive student support. Recent practice guidelines have called on school counselors to build and maintain these linkages (ASCA, 1997, 2003; Campbell & Dahir, 1997).

Focus of This Chapter

This chapter will examine the role of school counselors in fostering and supporting school–community agency partnerships. After reviewing the evolution of school–community partnerships, with particular emphasis on their contribution to shaping the role of school counselors over decades, the chapter will discuss the fundamental developmental principles that simultaneously inform school–community partnerships and guide the practice of school counselors in this area. Following a discussion of the challenges inherent in school–community partnerships, the chapter will review "best practices" for the planning, imple-

mentation, and evaluation of school–community partnerships. Finally, this chapter will conclude with a discussion of the various models of school–community partnerships.

Brief History of School–Community Agency Partnerships

Historically, schools have long been aware of the need to respond to the nonacademic issues that can result in nonacademic barriers to learning (e.g., medical, social/environmental, emotional, familial concerns). Confronted by the pervasive effects of environmental stressors on learning and behavior, schools have traditionally sought to lessen the impact and address the consequences of those stressors on students. As early as 1890, reformers were advocating the provision of medical and dental examinations, lunches, summer programs, recreational activities, and child welfare officers in American schools (Tyack, 1992). In response, school systems gradually began to address a range of children's developmental, health, and nutritional needs. By 1940, annual medical and dental exams were provided, and school lunches became the norm by 1950 (Myrick, 1993; Tyack). While federal and local funding supported these efforts, the schools served as the primary locus and manager of the delivery of services.

As the decades progressed, federal and state governments began to increase funding to community-based agencies to address some of these needs (e.g., through entitlement programs for health care through Medicaid and for nutrition through the Food Stamp Program). In recent years, government-supported community health and mental health centers, hospitals, and social service agencies have provided an array of services to families and children. Neighborhood health centers, for example, now provide health care to a significant number of poor children. With the advent of these programs, the extent to which the school was held responsible for the delivery of comprehensive services decreased. This shift in responsibility is evident, for example, in the steady decrease in the number of school doctors over the past several decades.

While the government has supported the efforts of community agencies to increase care for the physical health needs of children, it has not been as responsive to their psychological needs. Recognizing that unmet psychological needs impact learning in significant ways, schools have made substantial efforts to respond to the mental health needs of children and families. Particularly in the last two decades, prevention and intervention programs in the domains of behavioral and emotional problems have expanded in local school systems. Schools are primary providers of mental health services to children. As a consequence, the profession of school guidance and counseling has evolved into a major provider of mental health services in schools (Gibson & Mitchell, 1990; Myrick, 1993; Short & Talley, 1997). What began as a profession devoted to preparing school children for the world of work broadened into one also dedicated to the adjustment of students to the demands of the school environment and then, gradually, assumed increasing responsibility for the emotional well-being of its students (Bauman, Davis, Falco, Seabolt, & Szymanski, 2003; Gibson & Mitchell; Myrick).

The growing demands for mental health services quickly exceeded the capacity of already overburdened school counselors, who were simultaneously responsible for group guidance, college advising, student scheduling, and many other tasks (Paisley & McMahon, 2001). As a result, counselors looked to community agencies, such as health care and mental health providers to form partnerships with the schools and assist with service delivery. Further, as school counselors recognized that fostering mental health requires a focus on prevention for all students, as well as intervention for the few, they sought out community partners who could provide supports and youth development opportunities (e.g., recreation, team-building, and sports). In recent years, the need for community partnerships with schools has intensified even more since the demands for increased academic achievement has led to cutbacks in a number of school-based student support services (e.g., counseling and health services, sports, art and music courses).

Why School–Community Partnerships Make Sense

Schools Cannot Do It Alone

The No Child Left Behind (NCLB) legislation (2001) has brought educational reform to every classroom in the country. The goals of this legislation—for every child to achieve his or her maximum potential—have been addressed through the development of curriculum standards and frameworks and new strategies for teaching and learning. The focus on improving academic achievement has been intense with every state and district aligning curricula to the national standards and frameworks and implementing intensive standardized testing to assess student outcomes. However, 6 years after the introduction of NCLB legislation, the country is still faced with a substantial academic "achievement gap." The achievement gap is a significant disparity in academic test scores between students of color, particularly Black and Hispanic students, and White students, as well as between students who experience poverty and those who do not (Barton, 2001, 2003; Campbell & Brigman, 2005; Isaacs, 2003; Newsom, 2003). The achieve-

ment gap has existed for decades and continues to persist despite the focus on improving teaching and learning strategies that resulted from the implementation of NCLB. This discrepancy in achievement has been described as one of the great civil rights issues of our era. It reflects social inequities that systemically deprive students of color and students in poverty of access to the resources and opportunities that are critical to breaking the cycle of poverty (Schorr & Schorr, 1988).

There is growing acknowledgement that NCLB's nearly exclusive focus on teaching and learning will not be sufficient to close the achievement gap. As has been demonstrated over many decades, academic achievement is not the result of a single factor (e.g., classroom teaching, neighborhood resources, family stability, genetic endowment, socioemotional development), but rather is the result of the complex interplay of all of these factors over the course of development. In her recent analysis, Linda Darling-Hammond (2000) estimated that improved teaching and learning practices account for about 40% to 60% of the achievement gap and that class size accounts for another 8%. The significant remainder of the achievement gap is thought to be accounted for by family and community issues (Darling-Hammond). Similarly, Rothstein (2004) argued that not only is there a range of factors (e.g., health risks, lack of educational enrichment opportunities, and home and neighborhood factors) contributing to the academic achievement gap, but that most of these factors are associated with poverty and constitute major obstacles to children's ability to learn.

Children living in poverty experience multiple nonacademic barriers to learning (Walsh & Murphy, 2003). For example, research demonstrates that children living in poverty are significantly limited in terms of their vocabulary and literacy levels (B. Hart & Risley, 2003). Children living in poverty are at high risk for obesity (Strauss & Pollack, 2001), which results in a number of health risks (e.g., asthma) and significant school absenteeism. In low-income children, vision problems are known to occur at twice the rate as in middle-income children (Rothstein, 2004). Further, children living in poverty are increasingly at risk for exposure to community violence, which has been shown to be negatively correlated with academic functioning (Walsh & Murphy). It is widely recognized that the emergence of the so-called "new morbidities" (e.g., sexual abuse, domestic and community violence, poverty, drug abuse, and homelessness; Bemak, 2000; Center for Mental Health in Schools, 2003; Dryfoos, 1990; Keys & Bemak, 1997) pose a a significant threat to children's well-being and ability to achieve in the classroom (Becker & Luthar, 2002; Greenberg et al., 2003; National Clearinghouse on Child Abuse and Neglect Information, 2004; Urban Institute, 2000).

While challenges to academic achievement are greatest for children living in poverty, the stakes are high for *all* of today's youth. The 2003 Youth Behavior Surveillance System update (Centers for Disease Control and Prevention [CDC], 2003) indicated that the a number of 14- to 17-year-olds in the United States are engaged in diverse problem behaviors. Results show that 45% of these students had drunk alcohol during the prior 30 days and 22% had smoked cigarettes and marijuana at least once during the prior 30 days. During the preceding 12 months, 33.2% had been involved in a physical fight; during the prior 30 days, 17% had carried a gun. Further, 46.7% had engaged in sexual intercourse; 37% of sexually active students had not used a condom at last sexual intercourse.

Reducing students' risks and enhancing their healthy development are challenges that need to be addressed. Schools rightfully acknowledge that they cannot do it alone and need the help of other institutions and resources (Lawson & Briar-Lawson, 1997; Payzant, 1992; Riley, 1998). Present-day educators, particularly school counselors, are quickly becoming aware of their need to join hands in an organized and deliberate manner with parents, community members, agency and clinic professionals, neighborhood organizations, institutions of higher education, and politicians in order to improve the life chances of children and youth (Alexander, Kruczek, Ramirez, & Zagelbaum, 2003; Carpenter-Aeby & Aeby, 2005; House & Hayes, 2002; Power, DuPaul, Shapiro, & Kazak, 2003; Williams, 2003).

Holistic Approach to Education

The critical role of school–community partnerships in supporting the learning and development of children is grounded in our current understanding of the human developmental process. Our best contemporary understandings of human development lead inevitably to the conclusion that no single societal institution or activity is sufficient to fully support the healthy development of our nation's children. Current understandings of human development serve not only as a conceptual basis for school–community partnerships, but also undergird the profession of school counseling (Akos, 2001; Galassi & Akos, 2004; Paisley, 2001).

For much of the 20th century, development was viewed as a universal process that unfolded in the same way for all children, regardless of the diversity of their experiences and environment. It is now recognized that development cannot be reduced to a series of stages that occur internally and universally, but rather is a product of a transaction between the child and his or her environments (Cicchetti & Sroufe, 2000). Further, emerging theoretical understandings view development as involving continuous interaction among the various domains of the child (i.e., biological, psychological,

and social), occurring across the life span, and involving both risk and protective factors (Ford & Lerner, 1992; Walsh, Galassi, Murphy, & Park-Taylor, 2002; Walsh, Howard, & Buckley, 1999). We will now describe how these developmental principles assist educators and school counselors to understand not only that partnerships with the community are critical, but also how to implement them in practice.

Role of context. Contemporary best practices in education assume that knowledge is not simply "imparted to the child" in a one-way interaction, but rather is coconstructed by the child within the social contexts of school, family, and community (Airasian & Walsh, 1997). For example, children's understanding of and response to literary narratives or social studies lessons are grounded in their individual experiences in family, neighborhood, and cultural/ethnic identity. The greater the extent to which the new knowledge is embedded in the familial, social, political, and cultural dimensions of the child's world, the better the fit with the child's existing cognitive structures and the more effective the instruction.

In a similar vein, student support interventions typically coordinated or implemented by school counselors are effective insofar as they reflect the unique contexts that have already shaped the child. While the delivery of health and mental health care may seem, on the surface, to be an abstract and universal practice, it is now widely recognized that the effectiveness of health care practices is grounded in the cultural and social context in which they are delivered (Lubeck, Jessub, deVries, & Post, 2001; Segal, 1995). The recognition that children's unique contexts significantly shape their development has led school counselors to incorporate multicultural competencies into their practices. Best practices in student support recognize that connections with community resources better equip schools and school counselors to deliver contextually meaningful supports (Dryfoos, 1994b; Paavola et al., 1995; Schorr, 1997).

Bio-psycho-social levels of development. The role of school counselors positions them to recognize the mutually influential interaction between the biological, psychological, and social domains within the individual. For example, they regularly see students whose access to the curriculum is limited by chronic illness or family violence (Stallings, 1995). However, in many service settings, this recognition of the interdependence of the biological, psychological, and social levels of development has often been difficult to translate into practice. Traditional service providers have typically focused on a single aspect of development to the exclusion of others. For example, in schools, educators have focused primarily on cognitive development, while physical and socioemotional development was left to other professions. While these distinctions between various domains of development often define the boundaries of the various professions, they are, at best, artificial. Developmental theorists have pointed to the holistic or unitary nature of development and consider the various domains of development (e.g., cognitive vs. affective, biological vs. psychological) as the consequence of the particular perspective or angle from which development is viewed rather than as a reflection of "true cuts of nature" (Overton, 1998).

The complex issues facing today's children, however, can rarely be divided into the "discipline-shaped boxes" of the different professions. An effective response to student problems requires the services of a range of professionals, most of whom do not exist within the school and whose varied services must be integrated and coordinated with one another. School counselors play a critical role in implementing coordinated, comprehensive systems of care that involve both school and community agency staff representing a range of professions.

Development across the life span. An understanding that development occurs throughout the life span supports school counselors' recognition that education is a lifelong process. Development does not stop at the end of childhood or adolescence. Therefore, school counselors recognize the responsibility to prepare students for their entry into adulthood, the world of work, and responsible citizenship (Briztman, 2005). Fulfilling these responsibilities continues the legacy of school counseling, which originally focused on guiding students in their school-to-work transitions.

The life-span approach to development also acknowledges that adults who parent children continue to learn and develop both cognitively and emotionally. Supporting parents to enhance their skills and competencies, which has long been part of school counselors' work, ultimately leads parents to more effectively support their child's academic and social development. Parents can benefit from a range of supports and services that are typically available in the community. School counselors can work to increase parents' access to community services as well as formal learning opportunities that continue their education (e.g., high school equivalency, English language learning (ELL), computer training).

Risk and protective factors. For a number of years, school counselors have struggled with determining whether to focus primarily on enhancing strengths or remediating deficits. In today's schools, significant financial and human resources are focused on students who fail standardized

tests. The focus on deficits in the academic arena is paralleled in the socioemotional realm as schools address a range of personal–social risks (e.g., drug taking, teen pregnancy, suicide). Unfortunately, within a deficit-focused system, schools with the highest achievement test failures have drastically cut art, sports, and other enrichment programs that support healthy development (Riley, 2002; Share, 2005).

The role of school counselors has been directly impacted by the strengths versus deficits debate. For decades, school counselors were viewed as the professionals who worked with students at risk. Fortunately, school counseling's close ties to the profession of counseling psychology helped school counselors in learning to maintain a strong recognition of the critical role of strengths in development. In recent years, as research on resilience and competence has demonstrated the powerful impact of strengths on development and learning, school counseling has become a clear voice for a simultaneous focus on both strengths and deficits at the educators' table (Benard, 1991; Education Trust, 2003; Garmezy, Masten, & Tellegen, 1984; Henderson & Milstein, 1996; Lerner, Walsh, & Howard, 1998).

Challenges in School–Community Partnerships

While early school–community partnerships were bold and important first steps in recognizing the potential of effective alliances between school and community, their shortcomings revealed chronic challenges inherent to this kind of collaborative endeavor. These challenges include (a) fragmentation and a limited range of services, (b) turf conflicts between school-based and community-based providers, and (c) insufficient funding.

Early partnerships often yielded a variety of discrete services, programs, and resources. For example, some community agencies provided programming in schools and classrooms that focused on a particular issue (e.g., bullying prevention). Some partnerships with local municipal agencies (e.g., police) addressed substance abuse prevention (e.g., the DARE project in the 1980s). Still others provided a service (e.g., mental health counseling) or youth development opportunity (e.g., YMCA recreation programs) for children and their families. As these partnerships began to multiply, many schools counted up to 20 or 30 community partners with whom they had one or another kind of collaborative arrangement.

While community partnerships significantly contribute to the school's capacity to support students, the proliferation of partnerships created significant challenges. The lack of coordination across partnerships often results in overlapping roles and functions. Community agencies can be unaware of the activities of other agencies in the school and unwittingly offer similar services or programs to the same populations of students. Services must be coordinated not only for the school as a whole, but also for individual students. It is not unheard of for individual students to be referred to duplicative services, which represents an inefficient use of resources and an ineffective way of addressing student problems. Oftentimes, aspects of student support that need a community partner (e.g., health education) may not be represented. The lack of integration and oversight typically results in fragmentation, duplication, and/or lack of services in key areas (Adelman & Taylor, 2002a; Lerner, 1995a).

The potential for community providers and their services to be marginalized within school operations presents an additional challenge to effective school–community partnerships. Over the years, school programs and services designed to address barriers to learning have often been viewed by school leaders as supplementary or auxiliary to the school's central mission of teaching and learning. Consequently, community providers often struggle to find their place in the day-to-day life of the school (Adelman & Taylor, 2002b; Osbourne & Collison, 1998). Further, external professionals may typically be pushed to the margins of school service provision as a result of turf conflicts with similar professionals in schools (e.g., community mental health professionals with school counselors and school psychologists). For example, school specialists might view agency professionals as discounting their own skills while external professionals may feel underappreciated and are sometimes not privy to knowledge about the unique culture of schools. These challenges require ongoing and honest conversations between in-school professionals (e.g., teachers, school counselors, and principals) and community agency professionals (e.g., mental health clinicians and social workers).

Finally, a significant challenge to the implementation of best practices in school–community partnerships is the lack of sufficient funding in both schools and community agencies. School-based funding for learning and healthy development is often eliminated or severely reduced when the school's budget tightens (Riley, 2002). At the same time, community agencies with similarly limited budgets struggle to make time spent in schools cost-effective by maximizing direct service hours to compile fee-for-service revenue. As a result, community agency representatives are often unable to devote time consistently to participating in school–agency staff meetings. This irregular participation is an obstacle for service coordination and efficiency.

School counselors are well situated to play a key role in addressing these challenges. Their training in the comprehensive needs of students, coupled with a systemic vision, places them in a unique position to facilitate the process of building and maintaining effective school–community partnerships and coordinating the services that result from

these partnerships. If school counselors are effective at coordinating services, the tension between internal school professionals and external service providers will likely be significantly reduced. The systemic perspective of school counselors will also help them to support school administrators as they raise funds sufficient to sustain these partnerships. Finally, having been trained in the importance of empirically validated programs, school counselors know the essential role of evaluation in maintaining the effectiveness of their student support services and sustaining partnerships.

Best Practices in School–Community Partnerships

To respond to the challenges presented by school–community partnerships as well as to facilitate effective partnerships, school counselors can call on the significant literature that identifies "best practices" in this area. A review of the literature suggests that effective school–community partnerships (a) set goals for partnerships that are aligned with the goals of education reform, (b) promote student support services that are comprehensive, (c) provide coordinated services for students, (d) offer a continuum of prevention and intervention services to all students, (e) offer developmentally appropriate student support services, (f) increase family engagement in schools, (g) enhance schools' and agencies' ability to recognize and respond to a diverse community, (h) evaluate the effectiveness of the student and family support services they deliver, (i) be sustained over the long term, and (j) be supported by an identifiable infrastructure.

Alignment with the goals of education reform. Effective school–community partnerships align their goals with the goals of the education reform agenda as articulated in the NCLB. At the broadest level, school–community partnerships work to improve not only students' healthy development, but also their academic performance. Community agencies can no longer consider their goals opposed to, or even distinct from, the goals of teachers and school staff to promote the academic achievement of all students. At the same time, educators can no longer view the promotion of academic achievement as a goal that can be achieved apart from promoting students' well-being. Healthy development—physical, psychological, and social—must be the goal of school and community agency staff. Similarly, academic achievement must be viewed as a major responsibility of both the school and the community. Committing to the twin goals of academic success and healthy development will promote well-functioning school–community partnerships in which partners contribute in complementary ways to shared goals

NCLB has identified school–community partnerships as essential to achieving the goals of education reform. As a core element of education reform, these partnerships are expected to employ NCLB's major approaches; that is, they must be integrated within the whole school improvement plan for each school and district, they must yield outcome data that informs practice, they must collectively serve all students, and also they must continually engage families.

Comprehensive student support. Effective school–community partnerships promote what has come to be one of the gold standards in school counseling, comprehensive student support (Adelman & Taylor, 2002b). Comprehensive approaches to care ensure that the full range of a student's needs—educational, medical, psychological, social, recreational, and legal—is met. By engaging an array of community partnerships, a single school or school district can provide the full range of services and supports. While each provider may offer only one or two targeted services, together they make a number of important supports available for students and families. These supports not only address risks confronting students (e.g., acute health care) but also promote healthy development (e.g., opportunities for youth development).

School counselors are well positioned to ensure that comprehensive services are available to students. School counselors became familiar with the notion of comprehensive approaches as far back as the 1970s. At that time, guidance counselors were encouraged to shift the focus of their work to a broad range of guidance activities conducted on a regular, planned, and systemic basis to assist students in achieving a range of competencies (Gysbers & Henderson, 2000). Although the immediate and crisis needs of students continued to be addressed, a major focus of the new guidance programs was to provide all students with a range of opportunities to support their development. Guidance programs were consequently expanded to include a comprehensive range of services, such as assessment, information, consultation, counseling, referral, placement, follow up, and follow through (Gysbers & Henderson). School counselors were now expected not only to provide direct service, but also to work in consultative and collaborative relationships with other members of the guidance team as well as with school staff and parents. Gradually, as it became clear that school staff could not provide for all of the needs of students, school counselors were encouraged to integrate the services of community agencies and institutions in order to build comprehensive systems that could address the full range of student needs (Brabeck, Walsh, Kenny, & Comilang, 1997).

Coordination of services. Effective school–community partnerships require that services be coordinated, thus eliminating discrete and fragmented services. In delivering services, providers engage in a collaborative approach. Coordination is more efficient and cost-effective because it avoids the unnecessary duplication of services and can reduce the number of providers involved with a particular family or a program (Walsh, Brabeck, & Howard, 1999). In addition, the positive outcomes that are likely to result from a coordinated approach will reduce the need for additional services in the future. When services are coordinated, students and families can avoid falling through the proverbial cracks.

As an effective practice, coordination of services can occur at many levels. For example, various school- and community-based professionals may collaborate in developing an intervention for an individual student. Coordinated systems of care do not leave the child and family to determine their needs and seek various services on their own but, rather, help families to identify their needs, access the appropriate services, and integrate the recommendations and treatments suggested (Walsh & Park-Taylor, 2003). Similarly, prevention programs that focus on all students can be collaboratively designed to incorporate a number of service providers. For example, effective violence prevention often requires the expertise of educational, psychological, social, and health providers.

School counselors are well prepared to become school leaders in the provision of coordinated services that draw from both school-based and community agency providers. Counselors' understanding of the importance of embedding individual services within a holistic framework of student supports and their experience coordinating services at the individual level, classroom level, and schoolwide level enable them to integrate comprehensive, coordinated student support into the mission of the school.

Continuum of prevention and intervention. Effective community partnerships should assist schools in offering a continuum of prevention and intervention services for students and their families. Ideally, school counseling programs should provide a wide variety of services, ranging from broad-based prevention services that promote healthy development for all students to narrowly focused treatment for students who suffer from severe or chronic issues (Green & Keys, 2001).

In practice, the continuum of supports and services is generally described in terms of three levels (Adelman & Taylor, 2002a). The first level focuses on primary prevention and positive youth development for all students (Weissberg & O'Brien, 2004); it is generally delivered through systemic whole-school programs (e.g., social competence curricula) or through community-based opportunities for positive youth development (e.g., Boys and Girls Clubs). For example, implementing health education programs can enhance the healthy development of students and prevent nonacademic barriers to learning that are associated with poor physical health and emotional distress (Marx, Wooley, & Northup, 1998; McKenzie & Richmond, 1998). The second level is a prevention/early intervention program designed to identify and address student issues soon after they develop. School counselors can serve students on this level by coordinating the development of programs for students with specific issues (e.g., bullying prevention and friendship groups). Finally, the third level is a system of care that treats the severe and chronic problems that students face through a web of in-school and community-based services (e.g., mental health counseling, special education, and medical care). Implementing programs and interventions at all of these levels requires the integration of school and community resources to provide the most effective support.

While school counselors traditionally focused on the needs of at-risk or special needs students, more recently they have come to view all students as their clients (Education Trust, 2003; Gysbers, 2001). This indicates an overall shift away from exclusively addressing individual student problems or crises toward providing prevention services that help to protect all students from developing problems that interfere with learning and growth opportunities (P. J. Hart & Jacobi, 1992; Lee, 2005). Though prevention services are critical, some argue that they do not sufficiently enhance the positive competencies of the student (Galassi & Akos, 2004; House & Martin, 1998). Consistent with developmental research on risk and resilience, these researchers urge school counselors to function as "developmental advocates" by fostering prosocial skills and problem-solving competencies (P. J. Hart & Jacobi; Masten, Best, & Garmezy, 1990; Werner & Smith, 1992). Effective school–community partnerships can sharpen this focus by renewing school counselors' awareness of the powerful role of strengths in the lives of children.

In addition to offering services that meet a range of needs (health, social, psychological, etc.), communities also bring a wide range of youth and family support programs to school–community partnerships. The natural assets of communities—youth serving organizations, sports leagues, part-time job opportunities, neighbors with special skills—provide the means for children and youth to build upon their strengths and enhance their resilience in the face of substantial risks to their development (Benson, 1997; Benson, Galbraith, & Espeland, 1998). Community-based youth development programs can work in partnership with the schools to assist individuals and groups of children to avoid poor outcomes and increase the likelihood of

good ones. Through their advocacy for school–community partnerships, school counselors can provide all students with opportunities to enhance their strengths and competencies and offer buffers to at-risk students that allow them to mature into healthy, well-functioning adults (Masten & Coatsworth, 1998; Rutter, 1985; Werner, 1989, 1990).

Expanding the capabilities of school counselors to treat all students as their clients should not detract from the services provided for at-risk students. Partnering with community agencies has positive results for students who struggle with emotional and behavioral needs. In the past, special education has been the default service for students with behavioral and emotional problems that interfered with learning. However, special education is not always the most effective way of addressing primary emotional and behavioral problems; the purpose of special education is to assist students with learning supports so that they can access the curriculum. Further, schools typically do not have the resources to address all of the complex emotional and behavioral needs of students and simultaneously provide support for and enhance the positive development of all students. By utilizing community services, the mental health needs of students are addressed more effectively and the school's resources are released to service the needs of all students (Kutash & Duchnowski, 2004).

Developmentally appropriate prevention and intervention. Effective school–community partnerships implement prevention and intervention programs that match the developmental tasks that students must negotiate. Schools are highly developmentally organized. They are aware of the developmental needs and abilities of children and tailor curriculum and instruction strategies accordingly. On the other hand, community agencies have less opportunity to shape interventions on the basis of sometimes subtle developmental distinctions among children. When school–community partnerships collaborate to design and implement prevention and intervention programs, the developmental expertise of schools is quite valuable. For example, many community agencies have faced challenges as they attempt to expand their after-school programs from elementary to middle school children. The after-school program model that was successful with elementary children is typically not efficacious with middle school children because of the developmental shift that occurs during the middle school transition. Through school–community partnerships, educational professionals can bring their extensive knowledge to bear on this issue and help agencies to design appropriate and successful programs for the middle school–aged group.

A developmental focus also informs prevention and intervention programs that support key transitions for students (Lerner & Kauffman, 1985). School counselors have long recognized that schools prepare students not simply for the next educational challenge, but for life. This recognition has led school counselors to support community partners that focus on the transition from school to work (Solberg, Howard, Blustein, & Close, 2004; Gysbers, 1997). While many high school graduates transition immediately into college, a large percentage move directly into jobs (Massachusetts Department of Education, 2004). Engaging the community to support critical developmental transitions is essential to providing the kind of education that will foster not only students' learning, but also their formation as responsible citizens (Betz, 1993; Chartrand, Strong, & Weitzman, 1995; Legum & Hoare, 2004).

Given that students' postsecondary transitions are largely influenced by the opportunities held by their particular environment, school counselors have engaged with community partners to provide systemic support for students' future planning (Lapan & Kosciulek, 2003; Lapan, Tucker, Kim, & Kosciulek, 2003). The School-to-Work Opportunities Act of 1994 advocated for the development of school-to-work community career systems, partnerships between the school and the community that create sustainable career opportunities for students (Hamilton & Hamilton, 1998). School counselors play a critical role in guiding students through the critical school-to-work transition. In fact, it has been shown that students who experience more adaptive transitions to work are more likely to have had school counselors play an active role in their career development process (Blustein, Phillips, Jobin-Davis, Finkelberg, & Roarke, 1997). School counselors can most effectively fill this important role in students' transitions by creating community career systems and reaching out to critical stakeholders in the community (e.g., parents, community leaders, businesses, and trade unions).

Family engagement. Effective school community partnerships extend supports not only to students but also to parents. The profession of school counseling is keenly aware of the significant role of programs that support parents (e.g., health promotion, ELL classes, continuing education, and parenting classes). These programs, often coordinated by school counselors in collaboration with community agencies, increase parental involvement in schools and educate parents about how to promote their children's academic achievement (Bryan & Holcomb-McCoy, 2004; Walsh et al., 1999).

The life-span orientation of school counselors has equipped them to direct the efforts of school–community partnerships toward supporting and enhancing the well-being of the adults in the community. The natural focus of schools on children and adolescents can often obscure the needs of their families. The linkage of school and community can create more opportunities for all professionals

to work directly with parents and other community-based adults who play a significant role in the development of young people. Many school–community partnerships have documented significant increases in family participation in joint school–community programs (e.g., Coltoff, 1998). Adult-focused programs provide school counselors with opportunities to engage parents more directly in promoting the academic achievement of their children. Schools counselors can help the school to go beyond the typical parent–teacher meetings in order to provide parents with a sense of ownership regarding the school and their children's progress. In many well-developed school–community partnerships, schools have invited parents and caregivers to join the planning process and serve as classroom aides for new after-school programs for children. Development of parent resource centers, which are organized and staffed by parents, can be greatly facilitated by the leadership of the school counselor. Parents' presence at the school communicates that they value education. The degree to which parents value education is a major predictor of academic achievement (Ferguson, Jimerson, & Dalton, 2001).

School–community partnerships also present opportunities that focus directly on parent education and support (e.g., computer classes and ELL instruction). Positive developmental opportunities for parents enhance the quality of family life and thus contribute to the academic and healthy development of children. Through school–community partnerships, school counselors can become aware of the needs of the parents as well as the resources of the community to address those needs. School counselors can be instrumental in developing after-school and evening programs that directly serve parents. On the basis of assessments of parents' needs and a mapping of community resources, many schools have been able to develop parent education programs such as ELL, computer training, and parenting strategies for behavior management. School–community partnerships allow school counselors the unique opportunity to have a voice in designing services for parents that may indirectly foster the positive development of children.

Recognition of diversity. Best practices in student support call for services that are tailored to the unique strengths and needs of students and families from diverse backgrounds—that is, children and families who differ in terms of race, culture, class, sexual orientation, language, etc. Although students from marginalized groups are profoundly impacted by the dominant group, acculturation is a bilateral process. Families of diverse backgrounds are not only impacted by, but also substantially impact, their environment (Atkinson & Thompson, 1992). The mutual interaction between various cultural/ethnic groups and the dominant culture changes everyone to some degree. Recognizing the importance of context is essential to multicultural competence because it allows school counselors to create school climates and interventions that promote positive racial, cultural, gender, and socioeconomic identities among children (Coleman & Baskin, 2003; Helms, 1990; Vargas & Koss-Chioino, 1992). Sink (2002) suggested that "School counselors should facilitate student development and enhance the total school and community environment through the understanding and appreciation of cultural diversities."

Recently, as a result of the recognition that diverse students have diverse needs, the school counseling profession has worked to become multiculturally competent (Holcomb-McCoy, 2005). School counselors have realized that they must reach out and connect with various resources in the community that reflect the diversity of the students within the school in order to accentuate their strengths and respond to their needs (Constantine & Yeh, 2001; Holcomb-McCoy & Mitchell, 2005). Further, involvement with a community that reflects the diversity of the school enhances the general school climate and allows individual students to have a greater sense of school belonging, which often leads to the improvement of academic achievement (Roeser, Midgley, & Urdan, 1996).

The work of school counselors is also greatly informed by the socioeconomic diversity of students. This particular aspect of diversity poses particular challenges to urban schools because of the high concentration of poverty in America's cities. Though context is universally influential in child development, students living in urban contexts face particular challenges in their development and education—challenges that reinforce the need for partnerships with community agencies and resources (Barnett, Conley, & Green, 2005; Bryan, 2005). School counseling in urban contexts calls for particular competencies that enable school counselors to meet the specific needs of urban students. Chief among these urban school counselor competencies is a systemic perspective and the ability to collaborate with community stakeholders (Hernandez & Seem, 2004; Lee, 2005).

The recognition that unique nonacademic barriers to learning emanate from the conditions of poverty leads to the realization that these barriers cannot be addressed solely by focusing on the student. Community partners must be involved in school counselors' efforts to assist students in overcoming challenges presented by the community (e.g., community violence and lack of access to medical care). Just as community problems contribute to nonacademic barriers to learning and student needs, community strengths in resources and diversity can help address students' needs as well as promote resiliency. School counselors recognize that the urban systems in which young people develop

should also be a center of attention for positive programming and intervention (Walz & Lee, 1998).

Evaluation of effectiveness. The growing mental health needs in schools have required school counseling to develop a broad repertoire of interventions to address both the issues facing at-risk children as well as prevention services aimed at a wider audience of students. As a consequence, the profession has built up a solid core of knowledge about the characteristics of effective interventions and prevention programs. Most school counselors recognize that interventions should be evidence based and should have defined and measurable outcomes.

In the face of a nearly limitless number of possible intervention and prevention strategies, school counselors can assist school–community partnerships to identify and implement research-based programs. In the selection of programs, school counselors facilitate community agencies' recognition that the most effective programs are based on an empirical assessment of the community's unique strengths and needs. Selection of evidence-based programming helps to focus the work of partnerships around specific, measurable outcomes. It helps partnerships to avoid global, nonfocused arrangements that operate on the assumption that programs of whatever type are good for children.

While evidence-based programs are effective in general, it is critical to determine effectiveness with specific populations and assess the fidelity of their implementation. Evaluation of program process and outcomes is an important dimension of the collaborative work of school–community partnerships. Accountability is particularly important to parents who want to be sure that their children and adolescents are receiving high-quality programs as well as to funders who are eager to ensure that their money is well spent.

Consistent with the approach of NCLB, evaluation data can inform the process of student support. Gathering and codifying this data can be a significant challenge to practitioners. School counselors often bring a range of skills to the evaluation process. Their training in research methods and statistics provides them with competencies and skills to make them effective collaborators in designing and implementing productive evaluations. They are also in a strong position to reach out to local university partners for support with research and evaluation. Evaluation of partnership programs can inform all providers of new and effective approaches to prevention and thus avoid wasting time and resources on less effective strategies.

Sustainability. In order to have maximum impact, effective school–community agency partnerships must be implemented over time. Abbreviated intervention and prevention programs have little lasting effect. The developmental research has made clear that change occurs over an extended period—not overnight. Only when partnerships exist over a significant period of time can the partners develop true reciprocity in that they learn to complement each other's strengths and limitations so that together they can maximize the potential for achieving positive outcomes for the school community.

In the past, partnerships between community agencies and schools were typically short lived, lasting as long as funding lasted. The older model in which either the school or the community agency was the sole source of funding often resulted in a lack of collaboration. Each partner would often feel that the other partner was not contributing its fair share. Recently, with funding shortages evident in education, health, and service sectors, new strategies for financial sustainability have evolved. Community agencies and schools have figured out creative ways to share positions that deliver services to children. In some school–community partnerships, third-party payers have provided funding for essential health services with schools and agencies collaborating in applying for these funds. For a number of partnerships, the federal government's after-school program—21st-Century Community Learning Centers federal program—has been a source of government funding to implement school-linked and school-based after-school programs. Corporations and foundations are increasingly stepping up to the table to support the development and at least short-term sustainability of these programs.

Sustainability is also enhanced by strategic utilization of specific resources in the community such as universities. In many communities, universities have brought considerable resources to school–community partnerships, particularly in terms of student interns (e.g., nurses, social workers, and counselors). It is recognized that financial resources are typically required for the operation of a school–community partnership; the synergies that arise from this partnership likely ensure that there is an overall financial saving. Operating the various units in the partnerships separately, without coordination, can be far more costly due to the lack of sharing resources.

Infrastructure. For many years successful school–community partnerships depended upon the time and effort of the principal as well as the time and effort of community agency administrators or staff in order for them to work smoothly and efficiently. However, the press of educational reform has all but consumed most principals in deepening the teaching and learning agenda of the school. Agency staff is similarly focused on delivering their primary service. For these reasons, attention to school–community partnerships is often marginalized in both school

and agency. Consequently, there is little time on either the school's or the agency's part to sustain effective programs. Effective school–community partnerships require an infrastructure whose major task is to focus on sustaining and nurturing the partnership.

School–community collaborative programs not only require time to design and deliver, but in order to maintain the partnership, attention to both product and process are necessary. Each partner needs an opportunity to make adjustments along the way. Each partner needs feedback about what is working and what is not, and each partner must engage in the process of evaluating outcomes. Collaborative efforts are ultimately successful only when the partners labor together.

Effective school–community partnerships require a deliberate focus on nurturing and sustaining the relationship. A designated infrastructure, an individual or team whose major focus is the relationship itself, can often play this role. Such an infrastructure will typically transcend changes in staff in both school and community agencies and will be the vehicle through which communication occurs. The infrastructure can exist in the form of a person or a team at each site who takes responsibility for school partnerships. Such an infrastructure develops processes for the collaboration to function more smoothly (e.g., memoranda of agreements, periodic reviews, and strategies for identifying problems or challenges).

The best practices of school–community partnerships can best be understood through a description of a program that embodies them. The best practices of school–community partnerships will look different when implemented in the varied contexts of school systems and with different school cultures and community populations. One example of a school–community partnership that strives to adhere to these best practices in its own particular context is Boston Connects.

Boston Connects: Best Practices in Action

The Boston Connects program is a school–community-university partnership that brings comprehensive, coordinated student support to 3,300 students in two Boston neighborhoods—Allston/Brighton and Missions Hill/Roxbury—by linking nine Boston public elementary schools with community and university partners. Though there are many community agencies involved with each individual school, the lead community agency partner of Boston Connects is the YMCA of Greater Boston. As a lead agency, the YMCA represents all community agencies on the Boston Connects implementation team. The university partner of Boston Connects is Boston College, with involvement from multiple schools and departments including the Schools of Education, Social Work, and Nursing and Management. The School Counseling Program, housed in the Counseling Psychology program, has played the major role in program design and implementation.

Boston Connects began in 1995 as an effort to extend services and resources (e.g., health, mental health, and family services; after-school programs; and youth development opportunities) in one Boston public school. The program was taken to scale in 2001, extending to eight more Boston public elementary schools located in two Boston neighborhoods. Over the past 6 years, Boston Connects has worked to promote the learning and development of students, 85% of whom are children of color and 70% of whom live in conditions of poverty. As Boston Connects has grown, it has maintained its commitment to embodying the best practices of school–community partnerships. Thus, it serves as one effective illustration for the best practices outlined in this chapter.

In accordance with the goals of education reform, the mission of Boston Connects is to build a comprehensive, coordinated, and systemic web of services in active collaboration with community agencies and schools in order to provide school children with the supports, services, and resources they need to be academically successful. Though this mission establishes students' increasing academic success as a foremost goal for the partnership, it also explicitly acknowledges that this end cannot be met without the simultaneous goal of supporting students' development and well-being. Thus, in addition to working directly to improve students' academic achievement, through educational interventions such as tutoring and special education, Boston Connects also works to reduce nonacademic barriers to learning by providing supports for students' social, emotional, and physical well-being.

Boston Connects strives to support students comprehensively. Prior to the full implementation of school–community agency partnerships in Boston Connects schools, options for responding to at-risk students were more limited. The typical outcome for students who experienced learning challenges was a referral for a special education evaluation. Though the appropriate service for some students, this referral was an inappropriate response for many others. One of the main successes of Boston Connects has been the decrease of the percentage of referrals for special education evaluations, coupled with the increase of the range of alternative services and supports offered to meet the comprehensive needs of students. At one point in Boston, 24% of the student population was labeled special education, with significant overrepresentation of children of color. Coupled with the district's intense effort to reduce special education referrals, the Boston Connects schools

have seen the percentage of children placed in special education drop to 14%.

Boston Connects has identified a wide array of prevention and early intervention programs for children who evidence some risk but are not appropriately classified as academically disabled. Among many others, these services include after-school programs, tutoring/academic support, mental health counseling, mentoring, health services, and summer school. Boston Connects has helped children to work through some of their challenges and receive supports from adults and peers in the community by dramatically increasing the number of students linked with a range of services. In just one academic year, from the fall of 2003 to the fall of 2004, the number of students receiving services and youth development resources increased by approximately 57%.

To ensure that the services and resources offered to students and families are coordinated, each Boston Connects school has a full-time school counselor, who is referred to within the program as a "school-site coordinator." A primary responsibility of this school counselor is the implementation of an effective student support process, through which each student, particularly those at risk, is assessed and referred for services and supports that enhance learning and development. The school counselor facilitates this process through the Student Support Team, an interdisciplinary group that consists of teachers, administrators, school counselors, and representatives from community partners, such as mental health agencies. This team assures not only that students are referred to appropriate prevention or intervention supports, but also that these services are not overlapping or redundant and routinely follow up with students, parents, and service providers. Further, the Student Support Information Database is a unique tool that enhances coordination of services by tracking referral information for each student.

In order to expand effective service and support connections for students, school counselors work with community agencies and other partners, always seeking to expand connections within the community. In this way, the school counselors create more opportunities for students to access various supports. By focusing efforts on coordinating services instead of the more traditional school counseling approach of delivering individual services (e.g., mental health counseling), school counselors can multiply the number of students served. Results from an analysis of the day-to-day activities of Boston Connects school counselors showed that activities supporting individual students (i.e., individual student appraisal and individual student services) composed 21% of all activities. Thus, school counselors were able to engage in a diverse array of other activities, such as family support and outreach (10%), school climate activities (14%), and service connections (29%; Walsh, Barrett, & DePaul, 2007).

The array of services and supports offered by Boston Connects falls along a continuum that ranges from whole-school prevention and youth development to small-group or classroom-level intervention for at-risk groups, and finally to early intervention for individual students exhibiting behavioral, emotional, or academic issues. A recent example of Boston Connects' whole-school prevention initiative is a health education and social competence curriculum that is currently being delivered to all students. This health program consists of two empirically validated curricula: (1) *Eat Well and Keep Moving*, the goal of which is to improve children's physical health knowledge, motivation, and efficacy and (2) *Skills for Growing*, which seeks to enhance students' social skills and emotional intelligence. Prevention specialists deliver the curriculum while raising awareness among the larger school community about the importance of physical and mental health. This initiative reflects Boston Connects' underlying philosophy that holds that children who are physically ill, fatigued, and undernourished cannot demonstrate their academic capacity, nor can students who are hampered by low self-esteem, poor emotional regulation, and inadequate social support. This curriculum seeks not only to educate, but also to empower students to care for themselves emotionally and physically.

In addition to whole-school supports, school counselors often organize and implement small-group services for classes or mixed-grade groups of students who demonstrate needs such as anger management or conflict resolution. Finally, individual students in need of services are identified through the prescribed Student Support Process and referred to services by the Student Support Team. These referrals are designed to meet the specific needs of the child and may include such recommendations as mental health counseling, a behavioral plan, or tutoring with university volunteers.

The continuum of prevention and intervention services constitutes the programmatic dimensions of what is referred to as "school climate." School climate reflects the physical and psychological aspects of the school that result in feelings and behaviors that can promote or impede learning. Social and emotional learning standards assist the school staff in identifying the developmentally appropriate behaviors that contribute to a positive school climate (Weissberg & O'Brien, 2004). One of the important roles of the school counselor is to facilitate the implementation of social and emotional learning standards and the development and maintenance of positive school climate.

The diversity of the perspectives represented on the interdisciplinary Student Support Team ensures that the supports offered to students are developmentally appropri-

ate. The teams, which typically comprise teachers, principals, parents, and learning support staff, are facilitated by school counselors. Collaboration among these diverse professionals who collectively work across the age spectrum in the school assures that all aspects of the child's developmental level will be considered in the review. Further, the social competence curriculum implemented by Boston Connects' school counselors weekly in each classroom is designed around the developmentally organized social and emotional standards developed by the Collaborative for Social and Emotional Learning (CASEL; Weissberg & O'Brien, 2004). Finally, Boston Connects' commitment to serving the whole child ensures that supports and services will attend to those developmental challenges that often occur largely beyond school walls.

As one of Boston Connects' four major goals, increasing family engagement is seen as a critical pathway toward helping students achieve success in the classroom and beyond. Inherent to Boston Connects' mission for supporting students is the recognition of the importance of building a community that centers around school life. The investment of parents and caregivers is central to making this a meaningfully supportive community for students. Boston Connects counselors work directly with parents by facilitating their connection to community resources and services as well as supporting their engagement in the academic progress of their children. School counselors also collaborate with school and community professionals to offer opportunities for parents to enhance their personal and career development (e.g., ESL, job, and immigration counseling classes at the school).

Given that 85% of the students attending Boston Connects schools are children of color and nearly two thirds speak a second language at home, it is critical that the partnership acknowledge and appreciate the role of culture and ethnicity. The school counselors and prevention specialists employed by the program must be responsive to the critical impact of culture and ethnicity on the various prevention and intervention programs. For example, in accordance with findings that cultural adaptations to prevention curricula are often necessary for effectiveness (Resnicow, Soler, Braithwaite, Ahluwalia, & Butler, 2000), the prevention specialists have modified the social competence curriculum to reflect the specific cultural and ethnic identities of the student community. As another example, school counselors learn to appreciate the different meanings of mental health diagnoses and interventions across various ethnic groups and, therefore assist families in accessing services from multiculturally competent clinicians.

Recognizing the importance of evaluating effectiveness, researchers at Boston College are conducting an ongoing assessment of Boston Connects in an effort to identify the program's successes and the students' successes and to help the partnership evolve. Outcome evaluations of Boston Connects quantitatively assess the partnership's progress toward its stated goals of improving academic achievement, as well as increasing community agency involvement in schools and creating a more diverse array of student support referrals for students. Data have shown advancement toward several of these ends. For example, the program has demonstrated a positive impact on academic achievement. Students who receive services are making gains at the same rate and sometimes at a faster rate than students who are not in need of student support services. Without services, it can be reasonably assumed that students at risk would continue to fall further behind.

Equally important to assessing these quantitatively measured outcomes is the process evaluation, which takes a qualitative look at the manner in which these services are implemented. Several programmatic aspects of Boston Connects are designed as avenues for gaining feedback from a cross-section of involved parties, such as school counselors, teachers, principals, and parents. This valuable feedback from those involved on the ground level has often been used to make changes, both large and small, to all aspects of the program from service delivery at the individual schools to the level of program infrastructure.

Boston Connects has demonstrated its sustainability by not only maintaining its partnerships, but also expanding them and shaping its interventions based on the community's changing needs and strengths. Boston Connects began as a partnership with one Boston public school in 1995 and has grown into a far-reaching systemic intervention. Boston Connects in its current form began in 2001 and was scaled up from one public school to nine. The partnership's presence in these schools for a number of years has allowed relationships between community partners and school professionals to deepen, thereby improving and expanding the services offered to students. In addition, the continued presence of the partnership, coupled with the ongoing evaluation, allows Boston Connects to adapt its services and supports in response to the evolving needs and strengths of the ever-changing community.

Infrastructure

Boston Connects is based on a collaborative model, and thus, leadership is shared among the various stakeholders of the partnership. The complex program infrastructure includes school-based Student Support Teams and full-time school counselors, a cluster-wide Student and Family Instructional Support Center, and a Resource Advisory Council.

At the individual school level, the school counselor represents the program and enlists the support school and community professionals for the Student Support

Team. This team reviews individual students and whole classes, making referrals and recommendations for student support.

The Student and Family Instructional Support Center systematically links families, schools, and community agencies across the neighborhood. It serves as a central location where family and student support services and programmatic activities are delivered based on identified needs. For example, one of the services offered by this center is registration. The Student and Family Instructional Support Center is the only non-Boston Public Schools registration site in this "cluster" of schools. The BPS site location is far from the Boston Connects neighborhoods and a difficult commute, especially when using public transportation, as many Boston Connects families do. Offering this service is critical for Boston Connects families because of the center's proximity to their neighborhoods.

The Resource Advisory Council is a team of community, school, and university representatives that provides oversight, leadership, and advocacy in the coordination, integration, and strengthening of student support services and school–agency partnerships.

Models of School–Community Partnerships

The effort to link schools and community has resulted in the development of a number of models of school–community partnerships. These models range from tinkering at the margins of existing models of schooling (e.g., systems for referral to community agencies) to comprehensive efforts to partner with the community at more intensive levels.

The least intrusive model of school–community collaboration is a school-linked services approach in which a school articulates formal linkages and agreements for services with community agencies and resources. Somewhat more extensive is a school-based services model that delivers the services within the confines of the school building or in adjacent or nearby locations (Dryfoos, 1996). A number of school-based models incorporate one particular type of service (e.g., a school-based health clinic) while others offer a wide range of services (e.g., a Family Resource Center) to support the academic programs. Some of these services operate under the aegis and budget of the school system while others are funded by local city or town health or human service programs.

More ambitious than school-linked and school-based service approaches are models that attempt to transform the school and its personnel in the direction of more comprehensive approaches to addressing the needs of students. One salient example of this approach can be found in the development of what are referred to as community schools. Community schools have been variously defined, but generally, they integrate education with supports necessary for the healthy development of children, family and communities. In short, these schools weave together community development initiatives and school reform (Dryfoos, 1994). Community schools take many forms including full-service schools and extended-services schools. They incorporate a variety of innovative strategies and programs that lead to comprehensive delivery of education and related health and human services. Some well-known exemplars include the Children's Aid Society Community Schools Programs and the Texas School of the Future Project. Several of these models are being adapted in various cities around the country (Wang & Kovach, 1996), and many involve a partnership with a local university that provides various types of assistance for the implementation of these community schools.

Critical to all of these models is the design and development of a core infrastructure that enables and sustains the school–community partnership. One of the most effective kinds of infrastructure is embedded within the school and is focused on two elements of school functioning: the Student Support Team and process and the School Climate Team and process (Walsh & Brabeck, 2006). The Student Support Team and process matches individual students with appropriate supports, resources, and/or services, while the School Climate Team and process organizes all the school prevention activities and implements the social competence curriculum.

While a wide variety of school–community partnership models exist, each with unique features, all such partnerships are built on a common set of assumptions about the nature of child development. Advocates of these partnerships recognize that the development of children and youth is inextricably linked to their home, school, and sociocultural environments (Bronfenbrenner, 1979) and cannot be understood in isolation from these contexts. The development of the child in one context (e.g., the school) will be influenced by the conditions of the other contexts (e.g., the family and community). Instead of employing a narrow focus on the intellectual achievement of school children, school–community partnerships assume that cognitive development cannot be separated from either biological or sociocultural development (Bronfenbrenner; Lerner, 1986, 1995b). It is also understood that the adults who are critical to the child's life are themselves developing and benefit from support by the local school and community (Lerner, 1986, 1995b). Enhancing the development of adults will indirectly support the development of their children. Finally, school–community partnerships recognize the role of resilience in the development of children. Community resources that foster the development

of children's strengths have been shown to contribute to improved academic outcomes (Masten et al., 1990; Werner, 1989, 1990).

These fundamental principles of development strongly suggest that not only the family but also the community must be part of the education of the whole child. A holistic view of human development makes clear that "it takes a village to raise a child" and it takes the partnership of family, school, and community to educate a child. School counselors, in their role as liaisons between teachers, parents, support personnel, and community resources, can be pivotal in forging strong school–community connections.

Vision of Schooling: The Whole Child

The most defining element of school–community partnerships that embody best practices and employ integrative models is their vision of schooling. School counselors' knowledge of students' biological, psychological, and social levels of development and their understanding of the impact of context, allows them to build school–community partnerships that champion a vision of schooling that sees, serves, and supports the whole child.

The division of the whole child into parts has framed the landscape in which school counselors have had to work over the years. Though unintentional, the assignment of teaching and learning (i.e., cognitive processes) to the schools and the personal–social needs of children (i.e., affective processes) to the community has become reified. On the one hand, there is little doubt that both educators and community providers are aware that cognitive and affective processes interact with and influence one another. On the other hand, as their roles have evolved, educators and community providers sometimes conducted their work as if these two processes were separate and unrelated aspects of the child (Eisner, 2005; Noddings, 2005). School–community partnerships redress this imbalance by deepening connections between school and community. Recognizing that children's development cannot be so simply divided, the school–community partnership movement has called on educators and human service professionals to recommit to a vision of the whole child.

In short, in helping to implement school–community partnerships, school counselors can restore to their role a balance between academic and personal–social emphases. The responsibility for enhancing academic as well as personal–social development renders the school counseling profession a critical part of the school's plan for educational reform (Gysbers, 2001; Gysbers & Henderson, 2000). In the context of school–community partnerships, school counselors can address the conditions that constitute barriers to learning and, at the same time, promote higher academic standards. This more balanced approach to education will lead school staff and community members to a renewed appreciation of both cognitive and affective needs of school children and to the necessity of linking the academic and personal–social domains (Marx et al., 1998; McKenzie & Richmond, 1998; Walsh et al., 1999).

The voice of the school counseling profession must be loud and unified in its call for the establishment and sustenance of interdependent community partnerships. In a culture that increasingly values individualism and autonomy, school counselors have recognized the undeniable truth that schools alone cannot provide optimal support for the healthy development of students. This recognition demonstrates not only their grounding in a unified professional philosophy but also, more importantly, their investment in the future of America's children and their unwavering commitment to enabling that future.

XLVI
LAW AND ETHICS IN SCHOOL COUNSELING

PATRICIA L. WOLLEAT
University of Wisconsin–Madison

The daily activities of school counselors take place within a complex of academic, social, cultural, political, legal, and professional influences (Remley, Hermann, & Huey, 2003), some of which are so basic to the functioning of schools as to be removed from the conscious awareness of students, staff, and the community; others are thrust into consciousness assuming a level of transparency that creates a palpable urgency to behave with deliberate consideration and reflection. The school counselor must have an appreciation both for the policies and practices that structure the foundational context and for the tools to deal ethically and effectively with the occasional dilemmas and crises.

The ethical challenges facing school counselors have been rendered immeasurably more complex as recognition of the diversity among their clients calls out for more sensitivity to the cultural context. Enrollment data illustrate the magnitude of this challenge. In 2002, 37.7% of enrolled elementary and secondary students were members of racial/ethnic minority groups, while among students in degree granting institutions of higher learning the percentage was 29.4%. These percentages have increased and continue to increase; for example, among fourth graders, 39.8% are racial/ethnic minorities, with 16.6% being African American and 17% being Hispanic. These data reflect the projected trends of increases, particularly in the Hispanic population. Whereas in 1999 the Hispanic population constituted 11%, by 2050 it is expected to be at 24%. The total racial/ethnic minority population is expected to top 50% by the middle of the 21st century.

The legal/ethical and cultural complexity of the context within which school counselors do their work distinguishes the role of professional school counselors from other counseling specialties and from other education professionals. Legally, the school is a unique institution, defined primarily by state law, with increasing influence of federal law. Layered in is also a tradition of local control of schools by elected school boards and other public officials and parental and citizen involvement in school affairs. Additionally, the primary clients are minors who lack the legal autonomy to make many types of decisions and instead are subject to the authority of their parents and the state. Thus, school counselors serve many interests, not the least of which is the professional belief (and cardinal ethical tenet) that a student/client's welfare is paramount as the anchoring principle of school counselor functioning, 1995; American School Counselor Association [ASCA], 2004).

School counselors vary considerably regarding both their awareness and their understanding of the contextual factors and in their perceptions of their competence to deal with a host of critical issues they may confront in their daily practice (Davis & Mickelson, 1994; Hermann, 2002). Among the highest frequency issues that school counselors reported confronting are deciding when to report child abuse, being pressured verbally to turn over confidential information, and determining whether a client poses a threat to self or others (Hermann). Davis and Mickelson noted that counselors were not always aware of the full array of issues in responding to specific scenarios relating to parental notification of alcohol and other drug abuse (AODA) issues, to release of student data to parents and third parties, to use of assessment tools outside of areas of competence, to participation in locker searches, and to work with clients who receive counseling elsewhere. These researchers also found, in part, that school counselors were more comfortable dealing with issues from an ethical perspective as compared with a legal perspective. This greater confidence in their ethical functioning may, in part, be a result of the tendency in professional training settings and the legal/ethical professional literature to focus on professional ethics (which are presumed univer-

sally applicable) as opposed to state law and local policies that vary from jurisdiction to jurisdiction. In addition, school counselors may experience a tension between the local aspects of their role (those rights and responsibilities that they share with other educators in their state and district that are regulated by state law and local policies) and the cosmopolitan dimensions that arise from their identification with the profession of school counseling across the country as embraced in professional codes of ethics (Davis & Mickelson; Pope & Bajt, 1988).

The goal of this chapter is to give school counselors a framework for understanding their professional responsibilities. While it cannot provide a treatise on every issue that may challenge school counselors, I hope that it will capture the necessary concepts and knowledge for analyzing at least the high frequency and emerging issues that may confront them. Optimally functioning school counselors are informed both by the best practice (Capuzzi, 2002) and by ethical traditions of the school counseling community, as well as by the laws and policies that regulate educational endeavors on federal, state, and local levels. Regional, cultural, political, and socioeconomic variability quickly dispels any hope, however, of a perfectly ordered world in which the interests of all parties seamlessly converge.

In order to shed light on this intricate mosaic of principles and policies, this chapter will be divided into four major sections: (1) a discussion of the major factors which compose the legal/ethical context of school counselor roles and functioning; (2) the sources of "regulation" affecting school counseling; (3) an explanation of some major ethical and legal concepts that are manifest in a variety of forms in the routine and not so routine transactions in which school counselors engage; and (4) a discussion of several situations fraught with complicated legal/ethical issues that are identified as high frequency in school counselors' work, are self-reported as issues in which school counselors lack confidence in their legal/ethical knowledge base, or are emergent issues that have been created by recent legal developments.

In addition to acquiring knowledge of ethical and legal principles, responsible school counselors understand how and when to apply them in a behavioral context. Toward this end, several authors have proposed protocols for ethical decision making (e.g., Cotlone & Claus, 2000; Eberlein, 1987; Keith-Spiegel & Koocher, 1985; Kitchener, 1984). Typically, these protocols delineate a series of decision-making steps, including to (a) describe the situation, (b) define the issues, (c) consult legal and ethical guidelines, (d) evaluate the rights and responsibilities of all parties, (e) generate possible alternative courses of action, (f) analyze the consequences of each alternative, (g) present evidence that the projected consequences will occur, and (h) make the decision.

A more culturally responsive framework was proposed by Hansen and Goldberg (1999). They supplemented the conventional protocols with a matrix that includes an emphasis on cultural and clinical considerations in addition to the usual legal and ethical principles. Their seven considerations provide a framework for making culturally sensitive ethical decisions and include (1) moral principles and personal values; (2) clinical and cultural considerations; (3) ethics codes; (4) agency or employer policies; (5) federal, state, and local statutes; (6) rules and regulations; and (7) case law.

The addition of the *clinical and cultural* strand to the ethical decision-making protocol represents a first step in infusing multiculturalism into ethical decision making. Toporek and Williams (2006) proposed three additional measures: (a) clearer and more direct language in ethical codes for professionals to address social injustice, (b) guidelines for ethical decision making that reflect social justice, and (c) adjustments in training programs to broaden professionals' competencies by incorporating social justice interventions.

Although legal standards have yet to be established in the multicultural arena, there is no longer any question that ethical competence as a school counselor includes multicultural competence (Arrendondo & Toporek, 2004). Meeting multicultural competence standards (and their progeny) as proposed, for example, by Sue, Arrendondo, and McDavis (1992) and the American Psychological Association (APA; 2003) are excellent ways to ensure that a threshold of competence has been attained.

Because the professional responsibilities of school counselors are enacted against a matrix of interacting and sometimes competing regulatory policies and procedures promulgated within a complex, multicultural context, school counselors are often called upon to rationalize these discordant strands. This process of resolving potentially competing policies creates the opportunity for what Jacob-Timm and Hartshorne (1998) called "quality control" (p. 1). Some of these principles may appear to be constraints on professional behavior; viewed from another perspective, some may actually be considered to empower the counselors by freeing them from having to deliberate on and defend every action they take; others may be legitimately experienced as thwarting the goals and mission of school counseling.

Probably few professions are as subject to external constraints as school counseling is. One of the goals of this chapter is to identify these various sources of regulation and identify how they are implemented and enforced. How has school counseling become the subject of so much regulation and what are the sources of these constraints?

The Sociolegal Context of School Counseling

Three major social conditions account for the uniqueness of the school counselor role and school counselors' professional responsibilities: (a) the fact that most of the clients of school counselors are minors who legally lack autonomy (see Kaczmarek, 2000), being subject instead to the authority of their parents and the state; (b) the nature of the public school as a political institution, publicly funded and controlled by legislatures and elected boards; and (c) the long tradition of school counselors' professionally organizing at the local, state, and national levels. Each of these influences enters into the regulatory equation, resulting in a matrix of rights and responsibilities that together provide the foundation for the daily activities of the school counselor.

Minors' Autonomy

Children and adolescents possess remarkably few independent constitutional rights, their rights instead being derived from those of their parents and the state (Levesque, 2002). The historical view of children was that they were the property of their parents (usually the father), who could discipline, abuse, and even sell their children into slavery without interference by the state (Kramer, 1994). The interests of children were presumed to be coterminous with those of their parents; for example, if the parents had no rights, neither did the children. The trajectory of children's rights has been in the direction from the status of *property* to the status of *person*. However, even today**,** the rights of children remain limited and nebulous, being largely subservient to the authority of their parents and the state.

The evolution of the rights of children has taken place within the context of three limitations on children's autonomy (Levesque, 2002; Nurcombe & Partlett, 1994): (a) the parental presumption or the rights of parents, which are primary; (b) the *parens patriae* principle (i.e., the state is the parent) that empowers the state to act in the place of parents; and (c) the *police power* of the state**,** which allows the state to protect the community—adults and children alike—in the areas of public health, safety, welfare, and morals.

The earliest acknowledgement of children's rights separate from their parents came in the form of recognizing the *parens patriae* power of the state to step in to protect the child when the interests of the child diverged from those of their parents, the parents could not meet the needs of the child, or the child was being exploited by the newly industrialized society (Kramer**,** 1994). However, the rights of parents to control and raise their children as they saw fit remained paramount to the *parens patriae* power of the state. Children belonged to their parents and to the state but did not have rights as individual persons. When the state exercised its power, it was justified by protecting society's interests, not necessarily those of the child.

The year 1967 marked the beginning of a new era of children's rights. At this time**,** there was some legal acknowledgement of children's rights vis-à-vis the state, without being derived from the parents. The first court cases that acknowledged that children have some independent rights were in the area of due process protections in juvenile justice proceedings. These cases (*In re Gault,* 1967; *Kent v. United States,* 1966) mandated that juvenile court proceedings must contain the due process protections of the rights (a) to counsel, (b) against self-incrimination, (c) to notice of the charges against them, and (d) to cross-examine witnesses. In addition to these due process constitutional protections, children have been given some "rights" by statutes in specific areas, for example, requiring their consent to treatment in some instances. But rights of children remain rooted in the family or in some other form of custody—if not parents, a guardian or the state.

Since 1967, there has been an expansion of children's rights (Kramer, 1994). In 1969, Justice Fortas declared that children are *persons* under the Constitution (*Tinker v. Des Moines Independent Community School District*, 1969). There does, however, remain ambivalence as to how children are viewed, often related to whether they are viewed as in need of protection (e.g., in child abuse reporting statutes) or if the child is alleged to have committed a crime (e.g., in Wisconsin, a 17-year-old is considered an adult for criminal prosecution purposes, but a child for reporting victims of child abuse). Professional ethical codes encourage the school counselor to promote the autonomy of children and adolescents in developmentally appropriate ways within this evolving legal context.

The Role of Government in Education

Governmental policies at various levels have a profound effect on the professional responsibilities of school counselors. Governmental policies must be premised on the rights that Americans are afforded through the Constitution. Among the major constitutional concepts at the foundation of the ethical and legal challenges that face school counselors are privacy, due process, and equal protection of the law. Privacy, which many constitutional scholars deem to be at the very core of personal rights and responsibilities, will be discussed at length later in the chapter in relation to confidentiality. Due process is the constitutional protection that requires persons to be granted hearings before their rights may be taken away.

Equal protection requires that laws be applied equally across persons. For much of the history of the United States,

unfortunately, equal protection has not always been honored—women, racial and ethnic minorities, GLBT individuals, and persons with disabilities have not always been treated equally under the law. Some of this discrimination has been dealt with by amending the Constitution (e.g., the 14th Amendment eliminating discrimination based on race); other bases of discrimination have been addressed by legislation. Among the important legislation applying equal protection principles in education are Title IX, which forbids discrimination in education on the basis of gender, and Individuals with Disabilities Education Act (IDEA), which grants a free and appropriate education to students with disabilities (see U.S. Department of Education Office of Civil Rights, 1991). The contemporary emphasis on multiculturalism in education and mental health interventions is a transformative outgrowth of the constitutional principles of equal protection.

Despite the growing role of the federal government in education, the most significant legal constraints on school counselors emanate from state and local laws and policies. "Public education is a creature of state law, usually mandated by state constitutions" (Kramer, 1994, Vol. 2, p. 434). This preeminence of state and local law is one of the reasons school counselors sometimes find their legal responsibilities confusing. Whereas federal laws and ethics codes of professional organizations have uniform nationwide application, state and local law is jurisdiction specific. Because of this variability across states and school districts, the literature on professional responsibilities tends to be heavily weighted toward ethical codes, federal legislation, and court decisions with nationwide application. Because it is a painstaking task to account for all the nuances in state law affecting the professional responsibilities of school counselors, some critical differences may be overlooked or minimized by authors, commentators, and counselor educators.

One of the foremost examples of jurisdictional variability of relevance to school counselors is state laws relating to child abuse. Although all states have some form of laws protecting children from abuse, they may differ in their specific contours in such areas as what behaviors or outcomes constitute child abuse and the circumstances under which mandatory reporting is required. It will not be possible in this chapter to delineate all of the specific differences in state laws. Instead, in this chapter, those areas of professional responsibilities that are the province of state law or local policy will be identified; school counselors are urged to get state- and local-specific advice on these issues.

Self-Regulation by Professional Communities

Although state and local laws vary across jurisdictions, all educators within a state's borders are subject to the same state laws and all educators in a given school district to the same board policies. However, members of different professions and disciplines within the same school may subscribe to different ethical codes. School counselors, for example, are represented by several professional organizations that have promulgated codes of ethics and developed mechanisms for adjudicating alleged ethical violations by their members (e.g., the American Counseling Association [ACA] and the ASCA). One Web site maintained by a prominent clinical psychologist (Pope, n.d.), to date, has identified over 100 ethical codes placed online by various psychological and mental health organizations. On the other hand, the professional organizations of some teaching disciplines promote no specific ethical codes, while special educators, administrators, and other student personnel professionals may be covered by ethical codes in various stages of development. The implication of this patchwork of ethical systems among different professions within a school means that the school counselor may at times be in ethical isolation, providing a lone voice advocating for a cherished ethical principle. This is not to say that other educators are behaving unethically or irresponsibly, only that the salience or relevance of particular ethical principles may be heightened for counselors as compared with other school professionals.

One of the most important functions that the national community of school counselors has performed is to advocate for all students. Consistent with the constitutional protection of equal protection, school counselors have also made a commitment to treat all students with respect and dignity. The preamble to the ASCA (2004) ethics code articulates this promise:

> Each person has the right to be respected, be treated with dignity and have access to a comprehensive school counseling program that advocates for and affirms all students from diverse populations regardless of ethnic/racial status, age, economic status, special needs, English as a second language or other language group, immigration status, sexual orientation, gender, gender identity/expression, family type, religious/spiritual identity and appearance. (Preamble)

ASCA's (2004) position is that counselors need to have the skills (e.g., see Constantine & Yeh, 2001) necessary to help members of all diverse populations to maximize their individual potential and to promote awareness and understanding of cultural and other sources of diversity in the school and community.

In summary, considering the minor status of school pupils, the preeminence of state and local law, and the heterogeneity of ethical systems across education profes-

sionals, it is not disputable that the school counselor exists within a very complex legal/ethical arena. In the rest of this chapter, we will deal with this complexity first, by identifying the sources of regulation or constraint and how the regulation is implemented and enforced, and second, by looking at some major ethical/legal concepts that cut across ethical decision making, and finally, by considering some specific situations that school counselors find to be highly prevalent or especially troubling

Sources of Regulation

It is eye opening and perhaps intimidating to consider the entire spectrum of entities that have something to say about how school counselors should go about their work. However, rather than being immobilized in the face of this multifaceted array of obligations and guidelines, counselors may be better served by attempting to understand the various interests that are advocated and how these interests may converge or diverge. It may be possible to reframe one's perceptions and see not just the constraints that are imposed, but also how the accumulated experience and wisdom of professional peers and elected officials may actually benefit and empower counselors to carry out their work more responsibly and efficiently. This efficiency may permit the counselors to serve more students more effectively. The sources of regulation of school counseling will be presented in order of those with the most narrow (but, perhaps, most powerful) scope of influence, for example, personal values, and proceed to those that are external and have more universal application, for example, federal legislation.

Values: Personal and Cultural

Professionally responsible behavior begins with the moral character of the school counselor (see Cohen & Cohen, 1999). Jordan and Meara (1999) asserted, "Principles, technical skills, and legal knowledge are necessary in evaluating a course of action but are not logically sufficient or necessarily primary. What is demanded of professionals is a dimension of character appropriately understood by way of virtues" (p. 144). Meara, Schmidt, and Day (1996) described the virtuous agent in the following words:

> One who (a) is motivated to do what is good, (b) possesses vision and discernment, (c) realizes the role of affect or emotion in assessing or judging proper conduct, (d) has a high degree of self-understanding and awareness, and, perhaps most importantly is connected with and understands the mores of community in moral decision making, policy setting and character development, and is alert to the legitimacy of client diversity in these respects. (pp. 28–29)

In distinguishing virtue ethics from principle ethics, the approach to ethical understanding embodied in most professional ethics codes, Jordan and Meara (1999) suggested that an appropriate question for examining virtue ethics is "Who am I?" as compared with "What should I do?"—the essential question related to principle ethics. Barnett (n.d.), following Kitchener's (1984) work on meta-ethics, proposed the following as the virtues that should underlie all ethics codes and ethical decisions:

> **Beneficence** is the virtue of helping others and providing services that are in the other individual's best interest; to do good. **Nonmalfeasance** is the virtue of not doing harm; ensuring that our actions do not result in harm to anyone. **Fidelity** is the virtue of faithfulness; being true to our commitments and obligations to others. A component of fidelity, **veracity**, implies we will be truthful and honest in all our endeavors. Promoting the **autonomy** of those we provide services to is one of our profession's overarching goals. **Justice** is the virtue of providing equal access to services and equal quality of services to all those with whom we come in contact. The virtue of **self-interest** stresses the importance of adequate and appropriate attention to our own self-care so our competence and judgment do not become impaired. (¶. 3)

Awareness of personal values and acting in congruence with universal virtues are necessary but not sufficient conditions for ethically responsible counselors. The culturally competent counselor must also have knowledge of the cultural value systems of their clients. Although the dimensions on which cultural values differ are manifold, many of them are captured in the dichotomy of *individualistic* (e.g., Eurocentric) versus *collectivistic* (e.g., Afrocentric) worldviews. Lu (1998) distinguished the individualistic worldview from the collective worldview on the basis of the weights cultures assign to individual versus group goals. The I/C dichotomy encompasses many specific cultural values such as the role of the family.

Clinical and Cultural Consideration

As noted earlier, Hansen and Goldberg (1999) added a major step in the ethical decision-making paradigm—considering the contextual cultural and clinical aspects of a situation. According to these authors, clinical judgment is involved in any "legal-ethical quandary," although most

ethical decision-making protocols do not include it. Downing Hansen and Goldberg illustrated the interrelatedness of ethics and clinical judgment using the following example—the importance of a counselor's discerning, for example, whether a suicidal crisis is a genuine emergency or an attempt at manipulation. Another clinical consideration involves the developmental stage of the client. Ethically, competence requires that one adapt interventions and informed consent procedures to the age and cognitive competence of the client. Making treatment decisions informed by ethical principles is at the core of the ethical principle of competence.

According to Hansen and Goldberg (1999), "Cultural considerations are likewise often ignored or minimized when identifying salient variables, issues, and guidelines" (p. 496). They observed, "Issues such as the nature of multiple relationships, the use of barter, and boundaries of confidentiality take on different meaning when viewed from an informed multicultural perspective" (p. 497).

One of the most complete expositions of ethical quandaries viewed from a multicultural perspective was provided by Sadeghi, Fischer, and House (2003). Using a Delphi technique, they identified eight ethical dilemmas in multicultural counseling that are viewed as very important by counselors, most of whom work with a diverse set of clients. Most of these dilemmas arise from conflict between an individualistic worldview (which may be held by a majority counselor) and a collective worldview (which may represent the culture of a client). Although all of these dilemmas may not be directly relevant to the work of school counselors, they represent the extent to which ethics and multiculturalism are interrelated.

1. The counselor and client are faced with the client needing to choose between working on the symptoms of his or her emotional problems arising from a discrimination situation that has negative consequences, which conflicts with empowering the client to assert his or her civil rights although it would result in negative consequences for the individual.
2. The counselor and client are faced with the client's needing to choose between leaving his or her family to promote individual growth, which conflicts with assisting the client to stay and cope as a member of the cultural family.
3. The counselor and client are faced with the client needing to choose between ending an abusive relationship although it will result in him or her being a social outcast within the traditional culture, which conflicts with helping the client to stay in the marriage and cope with the situation.
4. The counselor and client are faced with the client needing to choose between seeking treatment based on Western medical practice to avoid negative health consequences, which conflicts with the client's cultural beliefs about health and illness.
5. Assisting a client with a problem while not having culturally specific competencies conflicts with not providing assistance although it could result in negative consequences for the individual.
6. Fostering independence of the client to solve his or her problems conflicts with the client's cultural expectation that the counselor offer solutions.
7. Achieving credibility with the client requires that the counselor compartmentalize his or her counseling values conflicts with the counselor maintaining his or her counseling values although the result would be a loss of credibility.
8. Using a standardized assessment is recognized by the funding agency to determine eligibility for treatment conflicts with using a culturally sensitive approach that is qualitative and more subjective and not recognized by the funding agency (Sadeghi et al., 2003, p. 185).

Among the dimensions of counselor functioning that potentially might be viewed through a cultural lens are assessment and diagnosis, goal setting, relationship parameters, intervention, and outcome evaluation. The ethically responsible school counselor has the competence to analyze each of these components from a multicultural perspective.

Local Policies

Whereas value, clinical, and cultural considerations focus on internal and case-specific dimensions, other relevant analyses involve external considerations. The most specific external level of influence is local policy and practice. Local control of public schools is an historic tradition in the United States. Although local school boards are increasingly subject to incentives and mandates from state and federal governments, much authority is vested in the local district to develop policies affecting both students and employees. Presumably local board policies are a reflection of community standards as school boards are elected entities. Given local control, policy differences might be expected across rural, urban, and suburban districts. Board policies may range from setting the calendar, to student discipline codes, to establishing the curriculum, and to developing personnel policies. Many of these board policies may directly affect the work of the school counselor, for example, their job descriptions and supervisory schemes—whether counselors are supervised by a central office guidance director or are evaluated by the school principal. Surprisingly, many school counselors are often more aware of state and

federal laws than of their own districts' policies. Yet, there is considerable variability in local policy and even federal legislation may permit school districts to formulate local policies as long as they are made public. School counselors are advised to become thoroughly familiar with local policies regarding such issues as client confidentiality, reporting child abuse, and dual relationships with students (e.g., some districts forbid staff from giving rides to students or inviting them to their homes). In addition, school counselors must become familiar with the mores and folkways of their respective communities. Formal policies are often accessible through student and employee handbooks; some, but not all, districts place their policies online and make them accessible to the public as well. Some districts provide for individual building autonomy, possibly adding another layer of administrative policy. Folkways and mores will typically not be available through written media; counselors must, instead, use their observation skills and seek consultation with mentors to gain appreciation of informal networks and sentiments of the community.

School counselors are urged to get as much information as possible concerning board and building policies before accepting a position, thus, possibly avoiding some conflicts between the counselor's personal/professional ethical positions and local policies. Although local policies cannot contravene law and a counselor should not be asked to comply with practices that are patently illegal, some policies may nonetheless be in conflict with professional ethics codes, which boards may not be legally obligated to follow. The ACA ethical code urges counselors to work toward congruence of law, policy, and ethics. However, if congruence cannot be attained, the school counselor should keep in mind that the penalty for violating board policies that are not illegal may be an action against the job.

State Law

Typically the next level of regulation comes at the state level. Although some state professional associations have promulgated ethical codes, the most significant regulation at the state level comes through legal mechanisms. Each of the three branches of state government has a hand in creating law that affects school counselors. School counselors are affected not only by the general statutes that affect all citizens but also by a special set of statutes, often called the "school code," which refers to public schools specifically. For our purpose, school code will refer both to statutes and to the rules and regulations developed by state education agencies that have been empowered by the legislature to create such rules. School codes cover a plethora of matters including, for example, (a) requiring and setting criteria for approving, denying, and suspending educator licenses; (b) approving counselor preparation programs that recommend counselors for the school counselor license; (c) setting standards for pupil/counselor ratios; (d) mandating the provision of certain counseling and guidance services; (e) nondiscrimination policies; (f) setting graduation and accountability standards; (g) providing privileged communication to clients of school counselors; and (h) implementing federal laws related to, for example, disclosure of pupil information (Family Educational Rights and Privacy Act [FERPA] of 1974), gender equity (Title IX), and services for students with disabilities (IDEA). In addition, school codes may set policies for funding of public education, including sources of funding and equalization formulas.

In addition to the school codes, other state laws affecting school counseling may include, for example, (a) mandating school counselors to be reporters of child abuse, (b) evidentiary rules that may recognize privileged communication for clients of school counselors, and (c) relationships among juvenile justice agencies and educational institutions. It cannot be stressed enough that state laws in these critical areas differ considerably, and it is a matter of ethical competence to become informed about the laws in the jurisdiction in which one practices.

State courts have also fashioned law that may affect school counselors through the imposition of liability for (a) failing to warn/protect third-party victims of client violence, (b) failing to prevent suicide (*Eisel v. Board of Education,* 1991), and (c) professional negligence or malpractice (*Sain v. Cedar Rapids Community School District,* 2001). Readers are cautioned that state law is highly variable and nowhere more so than in the areas just mentioned. Counselors are urged to get localized information regarding these potential venues for liability.

Depending on the nature of the state law or rule, various sanctions for a violation may be levied. For example, school counselors who violate the standards of their license may have their licenses suspended or revoked. Typically, the criteria for an action against a license fall into the categories of incompetence or immorality. The definitions of these criteria have been defined in Wisconsin law in PI 34.35(1)(c) and (d):

> (c) "Immoral conduct" means conduct or behavior which is contrary to commonly accepted moral or ethical standards and endangers the health, welfare, safety or education of any pupil.
>
> (d) "Incompetency" means a pattern of inadequate performance of duties or the lack of ability, legal qualifications or fitness to discharge required duties, and which endangers the health, welfare, safety or education of any pupil.

Other sanctions imposed by the state on individuals may include fines (e.g., for failing to report suspected child abuse or inappropriately disclosing confidential pupil information) or fines or withdrawal of financial support when a district violates a rule or law. School districts and, occasionally, individual counselors may be liable for claims for damages for harm to students as well.

The National Level

The final level of regulation is the national level. This level of regulation will be discussed in two parts—ethical codes as promulgated by professional organizations and federal law, both legislative and judicial.

Ethics Codes. A Web site maintained by Pope (n.d.), a noted authority on ethics in mental health, has identified nearly 100 codes of ethics promulgated by various mental health organizations. Such codes may be instructive to the public and to courts in the case of malpractice litigation and may be modeled by state licensing agencies as codes of conduct. Strictly speaking, however, professional ethical codes are enforceable only on and by their members. In their most fundamental sense, ethics codes are promises made to consumers that they will be treated with dignity and competence (see Hansen & Goldberg, 1999).

Jacob-Timm and Hartshorne (1998) asserted that ethical conduct is not synonymous with simple adherence to a set of ethical rules and standards. They pointed out, "Codes of ethics are imperfect guides to behavior" (p. 4). They cited the following reasons for their conclusion: (a) that ethics codes tend to be composed of broad abstract principles and are at times "vague and ambiguous" (p. 4); (b) that principles frequently compete with each other or with the law when applied to particular situations; and (c) that codes tend to be reactive, given the lengthy and thorough process by which codes are developed and amended. Within these limitations, Jacob-Timm and Hartshorne summarized the functions of ethical codes in ethical conduct as follows:

> Ethical codes thus provide guidance for the professional in his or her decision making. Ethical conduct, however, involves careful choices based on knowledge of codes and standards, ethical reasoning, and personal values. In many situations, more than one course of action is acceptable. In some situations, no course of action is completely satisfactory. In all situations, the responsibility for ethical conduct rests with the individual practitioner. (p. 4)

By tradition, school counselors have typically subscribed to the ACA (2005) *Code of Ethics and Standards of Practice* and the ASCA's (2004) *Ethical Standards for School Counselors.* These codes are compatible with each other, but the ASCA code is more specific in some areas that relate directly to working with minors in the schools, namely, responsibilities to parents, to colleagues, to associates, to the school, and to the community. In addition to the ethical code, ASCA has developed several formal positions statements covering the role of school counselors in such issues as HIV/AIDS, censorship, child abuse and neglect prevention, cross/multicultural counseling, parent consent for services, sexual orientation of youth, and students at risk.

Federal Law. Nationally, school counselors are impacted not only by their professional codes but also by federal law. The federal role in education is somewhat more complicated than that of the states because, under the common law, education was entrusted to parents and constitutionally it is a state function (Kramer, 1994). When Congress decides to enact legislation, it must find some constitutional authority to act. The concept of the "division of powers" between the federal and state governments as embodied in the 10th Amendment to the Constitution, reserves the function of education to the states. Thus, when Congress acts to regulate education it must do so indirectly through some other power. This is well exemplified in the National Defense Education Act (NDEA) of 1958, which is credited with providing funding to train the first significant cadre of school counselors in the 1960s (Herr, Cramer, & Niles, 2004). In this legislation, Congress used its *defense* powers to provide funding for education because the United States was behind the USSR in the race for space and it was believed that school counselors could help to identify and nurture scientifically and mathematically gifted students to aid in the national defense.

Since the early 1900s, the federal government has found ways to use its constitutional powers to regulate and provide financial assistance to schools, beginning with the Smith-Hughes Act in the early 1900s to provide for vocational education under the commerce power. Since NDEA, some of the most significant federal legislation that has affected the roles and functions of school counselors are the FERPA of 1974, which regulates disclosure of information from pupil records; Title IX, which provides for gender equity in all facets of education including career guidance and athletics; IDEA (formerly Public Law 94-142), which provides funds for educating students with disabilities; Sec. 504 of the Rehabilitation Act (USDE, 2007), which requires reasonable accommodations for persons with disabilities; and the Protection of Pupil Rights Amendment (PPRA, 2004), which requires parental consent for student par-

ticipation in required surveys and evaluations that ask the student to reveal certain personal and family information. The most recent federal legislation related to education, the No Child Left Behind Act of 2001, requires, among other things, greater accountability for student outcomes in reading and mathematics. Some of these federal laws will be discussed in more detail in later sections of the chapter.

Legal and Ethical Concepts

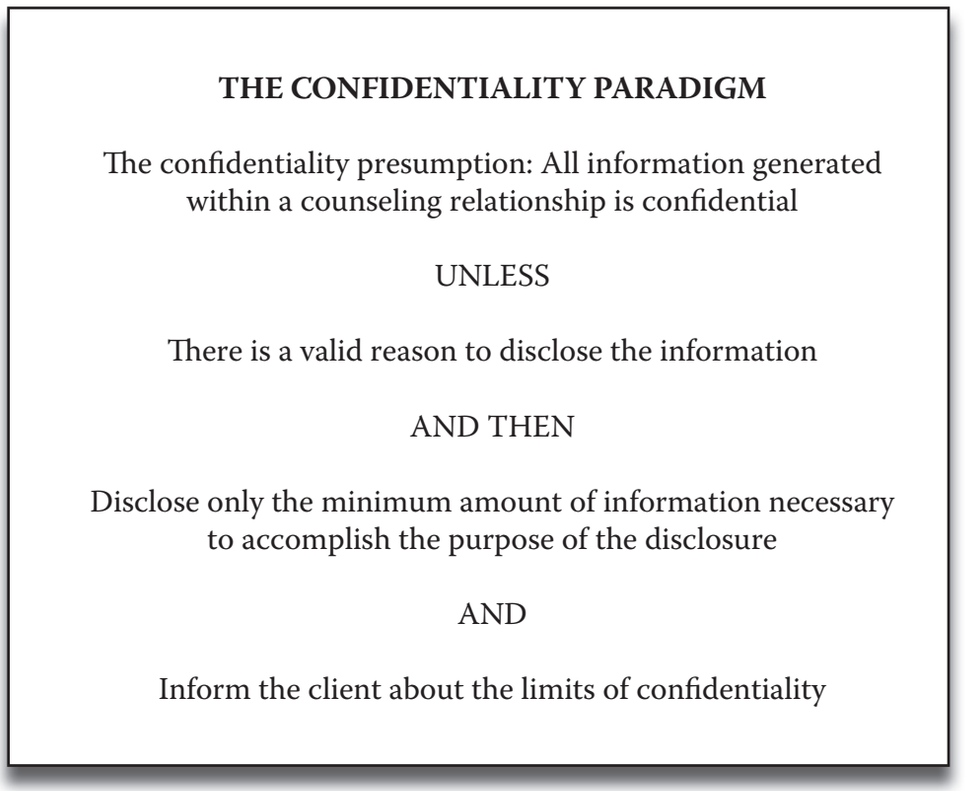
Confidentiality

Perhaps no other principle promoting client welfare is as important as confidentiality. Confidentiality in the counseling relationship is so important that it is embodied in nearly every mental health ethics code (see, e.g., ACA *Code of Ethics* sec. B and ASCA *Ethical Standards for School Counselors* sec. A.1.), federal statutes, (e.g., *Confidentiality of Alcohol and Drug Abuse Patient Records* (2003) and U.S. Department of Health and Human Services), and even in opinions of the U.S. Supreme Court (e.g., *Jaffee v. Redmond,* 1996). Ethically and legally, school counselors are obligated to prevent disclosure of all communication (oral and written) pertaining to the counseling relationship. As will be explained later, confidentiality, however, is not absolute, and counselors have an obligation to share the limitations of confidentiality with their clients.

In attempting to understand this very complex notion of confidentiality, Figure 46.1 is intended to capture the essence of confidentiality.

The Confidentiality Presumption. The presumption of confidentiality supports a belief in the primacy of privacy within a counseling relationship; thus, any disclosure of otherwise confidential information must emanate from a value position that supersedes the value of privacy. The primacy of privacy within professional counseling relationships is supported by three principles. First, although the word *privacy* is not explicitly contained in the Constitution, interpreters of the Constitution have considered privacy to be a fundamental right of Americans. The mantle of privacy grants autonomy in making decisions about one's body and mind. Thus, clients are presumptively in control of the extent to which they choose to share their thoughts and feelings with others and what happens to the communication that is generated within the professional relationship.

Second, privacy, as implemented through confidentiality, is a necessary condition for clients to seek counseling. Without the promise of confidentiality, people might be reluctant to seek counseling and, thus, possibly leave some problems unaddressed. The possibility that some people might be reluctant to seek help absent a promise of confidentiality was a major grounds for a decision by the U.S. Supreme Court in the *Jaffee v. Redmond* (1996) case, which



THE CONFIDENTIALITY PARADIGM
The confidentiality presumption: All information generated within a counseling relationship is confidential
UNLESS
There is a valid reason to disclose the information
AND THEN
Disclose only the minimum amount of information necessary to accomplish the purpose of the disclosure
AND
Inform the client about the limits of confidentiality

Figure 46.1 The confidentiality paradigm.

prevented a social worker from testifying in federal court about her counseling relationship with a police officer who had killed a man in the line of duty. The Court reasoned that police officers and other public officials may experience a high level of stress and anxiety in the course of their duties and that officials and the public alike benefit from the availability of counseling within a confidential relationship. The benefit of access to a confidential counseling relationship was indeed considered by the court to be sufficiently valuable that it overcame a fundamental tenet of our system of jurisprudence—access to all of the evidence in a legal proceeding.

A third principle supporting the need for confidentiality in counseling relationships recognizes that the promise of confidentiality promotes efficacy in mental health treatment. Given the potential benefits of counseling and psychotherapy, it is crucial that the conditions to maximize effectiveness are provided—one of these conditions is the promise of confidentiality. The Supreme Court in *Jaffee v. Redmond* (1996) opined,

> Treatment by a physician for physical ailments can often proceed successfully on the basis of a physical examination, information supplied by the patient, and the results of diagnostic tests. Effective psychotherapy, by contrast, depends upon an atmosphere of confidence and trust in which the patient is willing to make a frank and complete disclosure of facts, emotions, memories, and fears. Because of the sensitive nature of the problems for which individuals consult psychotherapists, disclosure of confidential communications made during counseling sessions may cause embarrassment or disgrace. For this reason, the mere possibility of disclosure may impede development of the confidential relationship necessary for successful treatment. (sec. 3)

In addition to the constitutional protections of confidentiality as interpreted by the judicial branch, Congress and state legislatures have also passed statutes that protect confidentiality of educational and medical information. The general trend in these laws has been to provide access to records by those whom the records concern and to limit access to third parties. Among these statutes are the FERPA, initially passed in 1974, relating to educational records, and the Health Insurance Portability and Accountability Act of 1996 (HIPAA; USDHHS, 2007), relating to personal health information. In addition, many states have passed their own versions of laws, compatible with FERPA, relating to confidentiality of educational records (e.g., Wis. Stat. 118.125), and many have their own laws protecting confidentiality of medical records as well (e.g., Wis. Stat. 146.81-84). And, of course, both the ACA and ASCA ethical codes assert that confidentiality is among the most central of ethical principles.

In summary, the presumption of confidentiality occupies an almost sacred place in the professional responsibilities of counselors. It has attained this status through its association with a fundamental constitutional right, its importance in a client's decision to seek help, and its role in maximizing the effectiveness of counseling.

Valid Reasons to Disclose Otherwise Confidential Information. Given both the social and pragmatic value of confidentiality, the decision to disclose information must rest on a competing value that society or an official policy maker deems important enough to overcome the presumption of confidentiality (Isaacs & Stone, 1999; Taylor & Adelman, 1998). In certain respects, these situations may be thought of as limitations of or exceptions to the general rule of confidentiality. Among the valid reasons to disclose otherwise confidential information are (a) with the informed consent of the client or client representative—in schools, almost always the parents; (b) mandatory reporting, for example, of child abuse; (c) imminent harm to self or others; (d) when permitted by statute; and (e) pursuant to a court order.

Consent for disclosure. It is probably not completely accurate to describe *consent* as an exception to the presumption of confidentiality as *no disclosure without consent* is at the heart of the presumption. But considering it as an exception does provide the opportunity to call attention to the fact that disclosure of otherwise confidential information sometimes appears to be so frequent in schools that it may appear that disclosure is the norm. It must not be forgotten, however, that in each case of disclosure some kind of authorization for disclosure is required—*with appropriate consent* constitutes one of the major forms of authorization for disclosure.

Four important issues enter into a consideration of consent for disclosure: (a) the nature of the information protected from unauthorized disclosure; (b) what constitutes consent; (c) who has the power to consent to disclosure—the school, parents, or students; and (d) subjects' access to information. (*Informed consent* will also be discussed later in the chapter in relation to consent for participation in counseling activities. *Informed consent for disclosure of confidential information* is an analogous, but narrower, concept.)

What information is protected from unauthorized disclosure? School counselors must be concerned about two types of information—educational information as defined, for example, by FERPA, and confidential informa-

tion (ACA, sec. B.1.C., 2005) or "information received in the counseling relationship" (ASCA, sec. A.2.f, 2004). Because FERPA authorizes disclosure of educational records without consent for certain purposes, for example, to school personnel who have a legitimate need to know, records that are personally kept by school counselors and that are not shared with others are not considered to be part of the educational record that falls under FERPA. Because these personal notes are likely to overlap with information that the ASCA and ACA codes consider confidential, school counselors can follow their professional ethics codes in deciding whether to disclose counseling information that is not covered by FERPA.

What constitutes consent? The professional ethics codes do not specifically define consent. However, there is a legal tradition in the medical and mental health fields as to what constitutes consent to disclose confidential information. Because giving consent to have otherwise confidential material disclosed involves surrendering the right to privacy, minimal standards for disclosure with consent must guarantee that the person is fully informed of the circumstances surrounding the disclosure and freely gives his or her consent. The FERPA requirements for consent for disclosure from a pupil's educational record are

> (a) The parent or eligible student shall provide a signed and dated written consent before an educational agency or institution discloses personally identifiable information from the student's education records. . . .
> (b) The written consent must:
> 1. Specify the records that may be disclosed;
> 2. State the purpose of the disclosure; and
> 3. Identify the party or class of parties to whom the disclosure may be made
> (c) When a disclosure is made under paragraph (a) of this section
> (1) If a parent or eligible student so requests, the educational agency or institution shall provide him or her with a copy of the records disclosed; and
> (2) If the parent of a student who is not an eligible student so requests, the agency or institution shall provide the student with a copy of the records disclosed. (34 C.F.R. 99.30)

Some state statutes and rules regarding informed consent might also include some specific date as to when the consent expires and a required notice to the recipient of the confidential information that the information must not be rereleased.

Who has the authority to consent to disclosure of counseling information? For the educational records of students under the age of 18, this authority is almost always going to be the parents. (Incidentally, FERPA gives this right to both parents unless there is a legal document that would limit access by one party; see U.S. Department of Education [USDE], 1999; Wilcoxon & Magnuson, 1999). FERPA expressly gives this right (and the right of access) to parents of pupils under 18 and, upon the student's reaching 18, to the student.

The issue of minors' rights to control information outside the scope of FERPA is less explicit, as state law and local policies may play a large role. State statutes may give minors over a certain age, often 14, the right to consent to disclosure of information from certain types of psychological treatment and to shield some information from parents or to require that both parents and minors consent to the release. It must be stressed, however, that these are very specific statutory rights and most do not pertain to the minor receiving services as a pupil in school (with perhaps the exception of AODA treatment). Nonetheless, school counselors should become familiar with the conditions under which minors may be able to give consent to the release of records independent from their parents in their own jurisdictions (Gustafson & McNamara, 1987). Counselors are also advised that it may be disrespectful to students to solicit their assent if refusal cannot be honored (Corrao & Melton, 1988).

For information generated within counseling that is not subject to FERPA, the school counselor may approach the issue of who has control of the disclosure of information with somewhat more flexibility in accordance with professional ethics codes (see Sullivan, Ramirez, Rae, Razo, & George, 2002). The ASCA (2004) ethics code presumes that disclosure of counseling information, when not required by law or imminent danger, will take place only with the consent of the student. The code also acknowledges, however, that the primacy of the duty to students must be balanced with the "inherent rights of parents to be the guiding voice in their children's lives" (sec. A.2.g; see also Mitchell, Disque, & Robertson, 2002).

> A.2.f. [The professional school counselor] protects the confidentiality of information received in the counseling relationship as specified by federal and state laws, written policies and applicable ethical standards. Such information is only to be revealed to others with the informed consent of the student, consistent with the counselor's ethical obligation.
>
> A.2.g [The professional school counselor] recognizes his/her primary obligation for confidentiality is to the student but balances that obligation

with an understanding of the legal and inherent rights of parents/guardians to be the guiding voice in their children's lives.

B.2. Parents/Guardians and Confidentiality

The professional school counselor:

a. Informs parents/guardians of the counselor's role with emphasis on the confidential nature of the counseling relationship between the counselor and student.
b. Recognizes that working with minors in a school setting may require counselors to collaborate with students' parents/guardians.
c. Provides parents/guardians with accurate, comprehensive and relevant information in an objective and caring manner, as is appropriate and consistent with ethical responsibilities to the student.
d. Makes reasonable efforts to honor the wishes of parents/guardians concerning information regarding the student, and in cases of divorce or separation exercises a good-faith effort to keep both parents informed with regard to critical information with the exception of a court order.

Access to records. The concept of privacy and the right to control personal information includes not only the right to consent to disclosure, but the right of access to the information as well. The major privacy protections, for example, for educational records (FERPA), student participation in nonacademic testing and evaluation (PPRA), and personal health information (HIPAA), have served to strengthen access to records or materials either by parents, in the case of minors, or to the student/patient. In addition, FERPA permits parents and nonminor students to challenge and, if necessary, to correct information contained in the educational record. Although, ethically, students should be given the opportunity to examine information that is disclosed with their consent, there do not appear to be any universal legal provisions that specifically require access to or the opportunity to correct counseling information not covered by FERPA although some states may have statutes that afford that opportunity.

Mandatory Reporting. The most typical occasion for mandatory reporting is in the case of suspected child abuse, although some states also require reporting suspected abuse of other vulnerable populations such as the elderly and persons with disabilities. A few states may require the disclosure of information related to other crimes as well. In Wisconsin, for example, a therapist is required to report prior sexual exploitation by a therapist (a felony) if the client consents. Every state has some version of mandatory reporting for suspected child abuse. Mandatory reporting of child abuse is one of the circumstances in which a public policy entity, usually a state legislature, has balanced the need for protecting children from harm with the need for confidentiality within certain professional relationships and has weighed in on the side of reporting (Lambie, 2005). In other words, where school counselors have been named as mandatory reporters, most, if not all, of their discretion to report has been curtailed. Consistent with the mandatory reporting statutes, the ASCA (2004) ethical code permits disclosure without the consent of the victim or parents when the law requires that a report be made:

> A.2.b. Keeps information confidential unless disclosure is required to prevent clear and imminent danger to the student or others or when legal requirements demand that confidential information be revealed. Counselors will consult with appropriate professionals when in doubt as to the validity of an exception.

There are both substantive and procedural differences across the states in these statutes, for example, how *abuse* is defined, whether "consensual" sexual contact between adolescents constitutes sexual abuse, whether the cultural background of the family is a mitigating factor, who the mandatory reporters are, the relationship of the reporter to the alleged victim, to whom reports are made, provisions for discretionary reporters, and sanctions for failing to report when required. School counselors are urged to become familiar with the contours of their own state's laws and local policies regarding reporting.

In order to encourage reporting, state statutes often provide immunity from all civil and criminal liability when a report is made in good faith. It is also the law in some states that employers may set up a reporting procedure that funnels reports through an intermediary, but it may be illegal to prevent an employee from reporting or to discipline an employee who does so in good faith.

Reporting suspected child abuse is a frequent legal/ethical issue confronted by school counselors (Hermann, 2002). Interestingly, it is also one in which counselors report a high level of confidence in their knowledge. Two possible hypotheses for the counselors' relative confidence in dealing with this issue are that confidence is gained by experience and/or that when a potential dilemma is codified into a law that requires a certain response, the ambiguity surrounding decision making is somewhat reduced.

Although some of the ambiguity regarding the decision to report has been reduced by legislation, the culturally sensitive counselor may also be confronted with conflicts

between legal definitions of reportable abuse and differences across cultures and families regarding appropriate measures for disciplining a child. The extent to which cultural background should be considered in reporting is the subject of a significant ideological debate. Some states acknowledge cultural differences in their statutes (e.g., California)—most are silent. Fontes (2005) provided a compelling analysis of how parental disciplinary behavior may viewed as either abusive or culturally normative as a function of the counselor's own cultural background. The culturally sensitive school counselor may partially approach this dilemma by taking a proactive role in educating parents about the standards to which their state will hold them accountable. Because child protection is primarily a function of state law, it is incumbent upon the ethically responsible counselor to become familiar with the laws of their jurisdiction. Further, because child protection laws are often enforced at the county or parish level, it is also critical that counselors become familiar with the social service and law enforcement policies in their local jurisdiction.

Imminent harm to self or others. Because counselors may have a legal duty to protect potential victims of clients' violence (e.g., *Tarasoff v. The Regents of the University of California,* 1976), ethical codes typically permit disclosure without consent when a client threatens harm to others. Unlike in the case of child abuse, however, the duty to protect third parties in most states is not statutory, but based on court decisions (e.g., the seminal case, *Tarasoff,* in California; *Schuster v. Altenberg,* 1988, in Wisconsin), and therefore, not only may the duty to protect be different across the 50 states, but the actions that are required when a client threatens violence are less clear. What is clear, in most states, is that either a court or a legislature has weighed the value of confidentiality against harm to a third party and has decided that confidentiality must give way to protection from harm when a client is determined to harm a third party. However, in many states, there are no named mandatory reporters or explicit procedures for reporting, thus leaving room for more discretion by individual professionals and for school boards to develop local policies for preventing violence in the schools. The ASCA (2004) code requires that confidentiality be breached in the case of imminent danger to self or others.

> A.7. Danger to Self or Others
>
> The professional school counselor:
>
> a. Informs parents/guardians or appropriate authorities when the student's condition indicates a clear and imminent danger to the student or others. This is to be done after careful deliberation and, where possible, after consultation with other counseling professionals.

Because the danger to self or others is an arena that is so saturated with state law and employer policies, school counselors are urged to get advice from experts on state law regarding the duty to protect in their own states. (Other issues related to dealing with high-risk individuals in schools will be discussed later in the chapter.)

The ACA and ASCA ethical codes, in addition to excepting imminent danger from confidentiality protection, have provided guidance on a specific type of potential harm—specifically, "to provide information to an identified third party who, by his/her relationship with the student, is at a high risk of contracting a disease that is commonly known to be communicable and fatal" (ASCA, sec. A.2.C). This provision also contains a caveat that some state laws may prevent this type of disclosure and, even if it is permitted, that warning be done with due regard for the client: The ASCA (2004) guidelines balance the need to disclose with the client's welfare:

> A.2.c. [The professional school counselor] in absence of state legislation expressly forbidding disclosure, considers the ethical responsibility to provide information to an identified third party who, by his/her relationship with the student, is at a high risk of contracting a disease that is commonly known to be communicable and fatal. Disclosure requires satisfaction of all of the following conditions:
>
> - Student identifies partner or the partner is highly identifiable
> - Counselor recommends the student notify partner and refrain from further high-risk behavior
> - Student refuses
> - Counselor informs the student of the intent to notify the partner
> - Counselor seeks legal consultation as to the legalities of informing the partner

Because of the stigma associated with certain infectious diseases (e.g., HIV/AIDS), many states have passed statutes that provide very high levels of confidentiality to medical information that concerns these diseases or have nondiscrimination policies that may protect those who are afflicted. Once again, it is the professional responsibility of the counselor to understand the laws of the state and local board policy regarding disclosure of this information and always to seek consultation before revealing this information.

Harm to self is another circumstance in which the principle of confidentiality is relaxed in the professional ethics codes. The need for confidentiality has been balanced against the potential loss of life by individuals who may not be prepared developmentally to act in their best interests. Although state courts have decided differently as to whether to impose legal liability on schools or school personnel (e.g., *Eisel*) for failing to prevent suicide, most commentators advise that when a school counselor becomes knowledgeable of a student's intent to commit suicide, confidentiality may be breached and the student's parents and school authorities must be notified (ASCA, 2004, sec. A.7.b; Remley & Sparkman, 1993). ASCA also recommended, if possible, student involvement in the disclosure process in the case of danger to both self and others.

> The professional school counselor:
>
> b. Will attempt to minimize threat to a student and may choose to 1) inform the student of actions to be taken, 2) involve the student in a three-way communication with parents/guardians when breaching confidentiality or 3) allow the student to have input as to how and to whom the breach will be made. (ASCA, sec. A.7.b)

Other aspects of the school counselor's role in suicide prevention will be discussed later in the chapter.

Disclosure without consent as authorized by statute. The ASCA (2004) ethical code promotes confidentiality unless there is consent or imminent danger, or disclosure is required by law or school policies. One example of authorizing disclosure without consent is in FERPA. Under FERPA, educational records (educational records do not include counseling information that is maintained by the counselor for his or her eyes only) may be released without consent in circumstances as explained by the Family Policy Compliance Office (FPCO) of the U.S. Department of Education (2002) agency charged with enforcing FERPA.

> Generally, schools must have written permission from the parent or eligible student in order to release any information from a student's education record. However, FERPA allows schools to disclose those records, without consent, to the following parties or under the following conditions (34 CFR § 99.31):
>
> - School officials with legitimate educational interest;
> - Other schools to which a student is transferring;
> - Specified officials for audit or evaluation purposes;
> - Appropriate parties in connection with financial aid to a student;
> - Organizations conducting certain studies for or on behalf of the school;
> - Accrediting organizations;
> - To comply with a judicial order or lawfully issued subpoena;
> - Appropriate officials in cases of health and safety emergencies; and
> - State and local authorities, within a juvenile justice system, pursuant to specific State law. (USDE, 2002)

Schools may disclose, without consent, "directory" information such as a student's name, address, telephone number, date of birth, place of birth, honors, awards, and dates of attendance. However, schools must tell parents and eligible students about directory information and allow parents and eligible students a reasonable amount of time to request that the school not disclose directory information about them. Schools must notify parents and eligible students annually of their rights under FERPA. The actual means of notification (e.g., special letter, inclusion in a PTA bulletin, student handbook, or newspaper article) is left to the discretion of each school.

Recent changes to FERPA because of No Child Left Behind Act of 2001 require that parents be given an opportunity to opt their children out of "activities involving the collection, disclosure, or use of personal information collected from students for the purpose of marketing or for selling that information, or otherwise providing that information to others for that purpose" (¶ 14). Barring opt out, a local education authority (LEA) is permitted to disclose information without prior consent in the following circumstances:

> The requirements concerning activities involving the collection and disclosure of personal information from students for marketing purposes do not apply to the collection, disclosure, or use of personal information collected from students for the exclusive purpose of developing, evaluating, or providing educational products or services for, or to, students or educational institutions, such as the following:
>
> - College or other postsecondary education recruitment, or military recruitment.
> - Book clubs, magazines, and programs providing access to low-cost literacy products.

- Curriculum and instructional materials used by elementary schools and secondary schools.
- Tests and assessments used by elementary schools and secondary schools to provide cognitive, evaluative, diagnostic, clinical, aptitude, or achievement information about students.
- The sale by students of products or services to raise funds for school-related or education-related activities.
- Student recognition programs. (USDE, 2002, p. 5)

The exclusion of the need for parental consent to disclose information to military recruiters will be discussed later in the chapter.

Pursuant to a court order. Counseling information that is subject to confidentiality protections may be sought in several types of legal proceedings, some of which may not be related to educational matters (James & DeVaney, 1995). School counselors have reported dealing with requests and orders to testify to be infrequent but to be among those areas in which they lack confidence (Hermann, 2002). Some of these circumstances might include disputed child custody cases, juvenile court proceedings, and malpractice and other civil suits. In these situations, the confidential information may be considered as evidence that is necessary for a just outcome in the litigation. Our system of jurisprudence requires that judges and juries have access to all of the information relevant to a dispute and excludes evidence only when some other social value is deemed more important. This principle of jurisprudence may be in conflict with ethical protections for confidentiality. In some instances, the client or parent of a minor client may waive confidentiality and give consent to the disclosure. However, if a client does not wish to waive confidentiality, the presumption of confidentiality requires that a school counselor do everything possible to protect the privacy interests of the client. The ASCA (2004) ethical code, for example, advises the counselor to request "of the court that disclosure not be required when the release of confidential information may potentially harm a student or the counseling relationship" (A.2.d).

By 1996, 16 states had given weight to pupils' and families' privacy rights by including licensed school counselors in privileged communication statutes relating to procedures in state courts (Fischer & Sorenson, 1996). The U.S. Supreme Court decision in *Jaffee v. Redmond* (1996) provided the privilege to clients of licensed social workers in federal court proceedings. Privileged communication "is the right of a person in a 'special relationship' to prevent the disclosure in legal proceedings of information given in confidence in the special relationship" (Fischer & Sorenson, p. 18). Although privileged communication may be afforded through constitutional guarantees of privacy and at the discretion of judges, the protection is usually more certain under a privileged communication statute.

In those states that have passed privileged communication statutes, the relationship between school counselors and their clients is given the same status as those between clients and physicians, attorneys, psychologists, and priests and between spouses. Like the general presumption of confidentiality, the right of privileged communication legally must give way in several circumstances, for example, in homicide trials, in child abuse proceedings, and when the client has made his or her mental condition an issue in his or her claim or defense. Some commentators have remarked that the exceptions are so numerous that they swallow the rule. Even with the exceptions, however, the possibility of a privilege does force a party seeking information to provide specific authority for the privilege to be inoperable and does permit an arena for negotiations regarding narrowing the scope of the information that must be disclosed, if disclosure is required by a court.

How should a school counselor respond when confronted with a request for confidential information? The answer to this depends upon from whom the request is coming and the authority of the request. The school counselor should always seek consultation regarding the validity of a request to disclose confidential information. James and Devaney (1995) provided the following guidelines for a counselor who may become a witness in a legal proceeding: (a) record dates and times and details of conversations with lawyers, (b) consider retaining one's own attorney, (c) seek legal advice to determine if requested records are protected by a privilege, (d) discuss and ascertain client's wishes about disclosure, and (e) inform judge of ethical principles regarding confidentiality.

Some novice school counselors may be intimidated in the face of requests from attorneys or when presented with subpoenas, but they are not required to respond to requests for confidential information from attorneys. When served with a subpoena, a counselor should respond that the requested information is confidential and according to the counselor's ethical principles may not be disclosed because of the harm to the client or counseling relationship that may result from the disclosure. Even in cases where the client or parents of a minor client has provided consent for disclosure, the counselor should seek consultation concerning the validity of the waiver and to determine precisely what information should be disclosed. In cases where the counselor is not certain that the client is aware of the information that the counselor may need to disclose, the client or client's attorney should be informed. The best advice is that the client or parents should be informed

whenever a disclosure is requested. In addition, FERPA very specifically requires that parents be notified when disclosure is requested pursuant to a valid subpoena or court order, as they may be entitled to a hearing on the issue. However, because the client is considered to be in control of counseling information, when a valid waiver of confidentiality does exist and/or clients/parents have been accorded their rights to notice and a hearing, such as is required under FERPA, the counselor is obliged to disclose the information.

The Minimum Necessary Rule

The minimum necessary rule requires that when there is a valid reason for a disclosure of information, the criterion for the nature and amount of information that should be disclosed is the minimum amount necessary to effectuate the purpose of the disclosure. The minimum necessary rule is expressed in the ACA and ASCA ethical codes and federal legislation such as HIPAA. There are several implications of this rule. First, it means that the framing of the consent document should be consistent with as limited a purpose as possible. Then, it means that the counselor, in consultation, should determine what information is essential for the purpose expressed in the waiver. Finally, it means that, just because a portion of a record may have been legally disclosed, other parts of the record are not automatically open to disclosure without authorization. Every disclosure requires specific authorization. A final corollary to the minimum necessary rule is that recipients of confidential information must be informed that they may not rerelease the information without consent from the client.

The Obligation to Discuss Limits of Confidentiality

As the protection of confidential information has become more formalized (e.g., through FERPA, PPRA) and more exceptions to confidentiality have been recognized, perhaps the most important obligation school counselors have regarding confidentiality is to ensure that clients understand the limits of confidentiality. The ASCA (2004) guidelines emphasize not only that limitations be discussed but also that "the meaning and limits of confidentiality are defined in developmentally appropriate terms to students" (A.2.a). This may be difficult when dealing with very young children; in these cases, the counselor may emphasize that any potential disclosure, however, will be in the context of helping the child (see Taylor & Adelman, 1989).

Consent for Treatment

Informed Consent Confidentiality of educational and counseling information may be thought of as one mechanism by which privacy is protected, informed consent for treatment/participation is another. Through informed consent, the client permits others to enter into his/her mental life and physical space. The legal history of informed consent to treatment stems from the common law notion that nonconsensual touching may give rise to a claim for assault and battery. Thus, in order to avoid a claim of battery, a physician, for example, would need to demonstrate that a patient had consented to the medical procedures performed. Today consent to treatment is also understood to be premised on the right to privacy, and in medicine, a failure to obtain informed consent can create malpractice liability. Counseling and psychotherapy are also considered treatments for which consent is required. The ASCA (2004) code requires that

> A.2. The professional school counselor
>
> a. Informs students of the purposes, goals, techniques and rules of procedure under which they may receive counseling at or before the time when the counseling relationship is entered. Disclosure notice includes the limits of confidentiality.

Neither the ACA or ASCA ethical guidelines explicitly state, however, that informed consent is *required* for participation in counseling. The ACA guidelines, in the section titled *Client Rights,* require two things that may, however amount to informed consent—*Disclosure to Clients* and *Freedom of Choice.* The term *voluntary informed consent* is used in connection with minor clients.

Disclosure to clients. When counseling is initiated, and throughout the counseling process as necessary, counselors inform clients of the purposes, goals, techniques, procedures, limitations, potential risks, and benefits of services to be performed and other pertinent information. Counselors take steps to ensure that clients understand the implications of diagnosis, the intended use of tests and reports, fees, and billing arrangements. Clients have the right to expect confidentiality and to be provided with an explanation of its limitations, including supervision and/or treatment team professionals; to obtain clear information about their case records; to participate in the ongoing counseling plans; and to refuse any recommended services and be advised of the consequences of such refusal (see ACA, 2005, sec. A.2.b)

Freedom of choice. Counselors offer clients the freedom to choose whether to enter into a counseling relationship and to determine which professional(s) will provide counseling. Restrictions that limit choices of clients are fully explained (see ACA, 2005, A.2.a.)

Inability to give consent. When counseling minors or persons unable to give voluntary informed consent, counselors act in these clients' best interests (see ACA, 2005, B.3).

Next to the question of the need for consent, the most salient consent to treatment issue for school counselors is "Who is authorized to give consent?" The issue typically boils down to the following questions: "Under what conditions is the minor client able to give consent?" and "When is the consent of parents or guardians necessary?" As the reader may surmise, there is not a one-size-fits-all answer to these questions. Rather, the answer depends on the particular matrix of ethics, law, and policy that apply in specific jurisdictions in conjunction with the developmental stage of the minor and the nature of the proposed intervention (e.g., in some states minors may access AODA and medical treatment for sexually transmitted diseases without parental consent). The school counselor should begin the search to answer this question by addressing any local school policies that may be in place regarding assurances or notices that have been provided to students or parents regarding the consent process for entering into a counseling relationship or other guidance activities. As will be discussed in more detail in the following section, both FERPA and the PPRA require that school districts annually provide notice to parents regarding certain rights of parents and pupils, including the right of parents to give prior consent for their children to participate in certain required information gathering activities. In addition, LEAs may choose to provide greater assurances for parental consent for their children's participation. Thus, the appropriate starting place is LEA policies regarding parental and student rights.

Both the ACA and ASCA codes give nod to the rights of parents but stop short of requiring parental consent for children's participation in counseling and guidance activities. The ACA (2005) code frames the issue in terms of parental *inclusion* in the counseling process:

> A.2.d. Inability to Give Consent
>
> When counseling minors or persons unable to give voluntary consent, counselors seek the assent of clients to services, and include them in decision making as appropriate. Counselors recognize the need to balance the ethical rights of clients to make choices, their capacity to give consent or assent to receive services, and parental or familial legal rights and responsibilities to protect these clients and make decisions on their behalf. The primary responsibility of counselors is to respect the dignity and to promote the welfare of clients.

The ASCA (2004) code more explicitly recognizes their responsibilities to parents/guardians, but also stops short of requiring their consent for their children's participation in counseling activities:

> B.1. The professional school counselor:
>
> a. Respects the rights and responsibilities of parents/guardians for their children and endeavors to establish, as appropriate, a collaborative relationship with parents/guardians to facilitate the student's maximum development.
> b. Adheres to laws, local guidelines and ethical standards of practice when assisting parents/guardians experiencing family difficulties that interfere with the student's effectiveness and welfare.
> c. Respects the confidentiality of parents/guardians.
> d. Is sensitive to diversity among families and recognizes that all parents/guardians, custodial and noncustodial, are vested with certain rights and responsibilities for the welfare of their children by virtue of their role and according to law.

The position of ASCA (1999) regarding the requirement for parental consent is perhaps more clearly stated in their position statement titled *The Professional School Counselor and Parent Consent for Services*. In this statement, ASCA took the position that parental consent is necessary only when required by law or local policy. At the same time, ASCA advocated that school counselors fully inform students and parents about the nature of their services, including the counselor's role, the nature of confidentiality, and the role of parents in a collaborative relationship.

In contrast to the ASCA position, the professional literature related to law and ethics for school psychologists assumes that parental consent is legally required in order to provide psychological services to minors (e. g., Jacobs-Timm & Hartshorne, 1998). They also proposed a secondary, but nonetheless important, developmentally appropriate role for minor clients to assent to the intervention as well. Jacobs-Timm and Hartshorne noted that there appears to be a legal trend toward greater levels of parental rights regarding their children's education.

One example of this trend toward a greater level of parental rights in the education of their children is the PPRA. This federal legislation began as the Hatch amend-

ment to the Elementary and Secondary Education Act (ESEA) of 1974, was modified by the Grassley Amendment in 1994, and in its current form is known as the Tiahrt Amendment to the No Child Left Behind Act of 2001. The PPRA is codified at 20 U.S.C. sec. 1232h and its regulations are contained in 34 CFR Part 98.4. According to the FPCO of the U.S. Department of Education (2002) office charged with enforcing FERPA and the PPRA, the PPRA applies to the need for prior parental consent for *required* student participation in certain activities (e.g., the administration of surveys, analyses, and evaluations, and psychological treatment) that have the purpose of revealing

1. political affiliations or beliefs of the student or the student's parent;
2. mental and psychological problems of the student or the student's family;
3. sex behavior or attitudes;
4. illegal, antisocial, self-incriminating, or demeaning behavior;
5. critical appraisals of other individuals with whom respondents have close family relationships;
6. legally recognized privileged or analogous relationships, such as those of lawyers, physicians, and ministers;
7. religious practices, affiliations, or beliefs of the student or student's parent; or
8. income (other than that required by law to determine eligibility for participation in a program or for receiving financial assistance under such program). (USBE, 2002, pp. 3–4)

The PPRA requires that schools and contractors also make available for inspection by parents instructional materials that will be used in connection with Department of Education (ED)-funded surveys, analyses, or evaluations. In addition to the consent and inspection provisions relating to *required* ED-funded surveys, the PPRA requires any elementary or secondary school that receives funds for any programs funded by the ED to develop, in conjunction with parents, policies regarding the following:

1. The right of parents to inspect, upon request, a survey created by a third party before the survey is administered or distributed by a school to students.
2. Arrangements to protect student privacy in the event of the administration of a survey to students, including the right of parents to inspect, upon request, the survey, if the survey contains one or more of the same eight items of information noted above.
3. The right of parents to inspect, upon request, any instructional material used as part of the educational curriculum for students.
4. The administration of physical examinations or screenings that the school may administer to students.
5. The collection, disclosure, or use of personal information collected from students for the purpose of marketing or selling, or otherwise providing the information to others for that purpose.
6. The right of parents to inspect, upon request, any instrument used in the collection of information, as described in number 5. (USDE, 2002, p. 4)

These policies must be communicated to parents annually, preferably at the beginning of the school year, and, in a timely fashion, any substantive changes to the policies. As part of the required notification parents must also be informed of the opportunity to "opt out" of the following:

- Activities involving the collection, disclosure, or use of personal information collected from students for the purpose of marketing or for selling that information, or otherwise providing that information to others for that purpose.
- The administration of any third party (non-Department of Education funded) survey containing one or more of the above described eight items of information.
- Any non-emergency, invasive physical examination or screening that is: 1) required as a condition of attendance; 2) administered by the school and scheduled by the school in advance; and not necessary to protect the immediate health and safety of the student, or of other students. (USDE, 2002, p. 5)

The penalties for violating the PPRA include a withdrawal of federal funding from the school district. Recent court decisions have made it quite clear that individuals do not have a private right of action to collect damages for personal harm under the PPRA (FPCO, 2002). Many advocates of family and student privacy rights consider the lack of a private right to enforcement and the fact that consent is not defined as informed consent to weaken federal privacy protections for families. At the same time, more parents and students are becoming aware of their rights under the PPRA and are assisted by the FPCO and many other private organizations advocating for families to maximize the PPRA protections (e.g., by providing models of letters that parents can send to their school district to obtain the rights that they have been afforded).

School counselors should take note of several implications of the current PPRA: (a) the trend toward greater protection of parental rights in education; (b) the requirement that many materials and activities employed by school counselors (e.g., for classroom guidance activities or mental health screening) may be included in mandated policies for parental consent or inspection of instructional materials, curriculum, and surveys and situations in which

opportunities for opting out may be required; (c) formal policies regarding requiring or exempting the need for parental consent for counseling and guidance activities will undoubtedly be more prevalent as LEA's are required to develop such policies if they already have not done so. The school counselor should be prepared to participate in the making of these policies from the perspective provided by their ethical codes, which place student welfare and developmentally appropriate levels of autonomy at the center. In addition, counselors might also advocate for the participation of parents and students in the formulation of these policies. The school counselor should also be reminded that their ethical principles may not be fully shared by other members of the educational community. Nonetheless, the professional counselor should continue to advocate those ethical principles and to continue to attempt to reconcile contrary policies with their ethical codes, keeping in mind, however, that despite their strong beliefs, violation of school board policy could result in personnel sanctions.

The Law of Negligence *Negligence* is a legal term that is applied to a situation in which a person who has a duty of care to another behaves in a way that falls below a standard of care and causes harm to the other. When a person commits negligence, he or she is considered to have committed a *tort*. When a professional commits negligence, the term *malpractice* is applied (Baerger, 2001). Most people are aware of the concept of professional negligence in the context of medical malpractice. Malpractice or professional negligence is also potentially applicable in the educational or counseling context. However, state courts have been hesitant to impose malpractice liability on schools for negligent teaching, for example, for failing to teach a student to read or not helping students to achieve certain achievement levels. Claims for educational malpractice have generally been foreclosed by the courts. On the other hand, claims about negligence that lead to physical injuries have a higher success rate.

Counselors may be somewhat more vulnerable than teachers to claims of negligence in their ongoing activities, but plaintiff victories remain few and far between. In a recent case (*Sain v. Cedar Rapids Community School District*, 2001) related to academic advising, the Iowa Supreme Court allowed a student to go to trial on claims that he had received inappropriate academic advising. On the other hand, plaintiffs (the individuals who have suffered the harm and are making the negligence claims) have had only a modicum of success in suits that attempt to place liability on the school or individual educators for failure to prevent violence or suicide (for a case where a school district was held liable, see *Eisel,* 1991). These issues will be discussed in more depth later in the chapter.

The potential for liability on the basis of negligence should not be disregarded by school counselors; at the same time, if they are in compliance with school policies, follow the principles and standards of practice of ACA and ASCA, and consult with supervisors and administrators when they have doubts, their risk of liability exposure will be lowered. It should also be noted that the legal principles relating to negligence and malpractice are matters of state law and cases decided in state courts are binding only in the state of origin. There is considerable variability across the states on many matters that relate to counselor's duties. It is, therefore, incumbent upon school counselors to get competent advice regarding their risk of liability for negligence in the areas that relate to their duties.

High Frequency Issues

Several studies surveying school counselors about the frequency of certain legal/ethical challenges and counselor confidence in dealing with those challenges have been conducted. A study by Hermann (2002) identified the following situations as ones that were either encountered by a high percentage of counselors or for which they do not feel well prepared: (a) identifying individuals who pose a danger to others, (b) identifying students who are at risk for suicide, (c) being asked to turn over verbal or written records, (d) determining whether to report suspected child abuse, (e) being subpoenaed to appear in a legal proceeding, and (f) expressing clients' dissatisfaction with counseling services. In this section, the first two of these issues will be considered, the others already having been discussed earlier in the chapter. The confidentiality and informed consent aspects of dealing with students at risk for suicide or posing a danger to others have been discussed earlier in the chapter but will be reviewed here and other dimensions of the issues will be identified. In addition, two emerging issues will be discussed in this section—the school counselor's obligation to present accurate information to students and the issues related to dealing with military recruiters in the school.

Because of the high stakes in many of these situations, the school counselor is urged to become thoroughly familiar with the professional literature on these issues. An excellent place to begin would be with the works cited in this chapter. Because of space limitations, only the very basic contours of these conflicts can be highlighted in this chapter.

Individuals Who Pose a Danger to Others

The school counselor must be concerned with at least two situations in which individuals may pose a danger to

others—when the harm may come to victims within the school and when the danger is to individuals outside the school. The differences between these two situations may be negligible as far as counselors' actions are concerned, but the counselor's authority to act may come from different sources.

Preventing school violence is a very high priority following several high-profile, multiple-victim homicides in schools during the past decade (Dwyer, Osher, & Warger, 1998; Lamberg, 1998; Riley & McDaniel, 2000; Smaby, 1995; see also U.S. Department of Health and Social Services, 2001). According to Hermann and Finn (2003) and Bailey (2001), school officials, including school counselors, have a legal obligation to take action when students pose a risk of danger to others. At the same time, courts have been somewhat reluctant to hold schools liable for student-to-student violence, at least that violence that is not foreseeable (Hermann & Remley, 2000). Nonetheless, schools may be on notice to take several precautionary measures in order to fulfill their duties to student and staff safety. At a minimum, actions must pass a *reasonableness* test; that is, school counselors are expected to exercise that degree of care that would be exercised by other school counselors with similar education and experience. Although counselors do have a role in preventing imminent violence, they also have an ethical obligation to protect the rights of students.

School counselors have at least two major roles in violence prevention—educating students and staff about violence and assessing the risk of violence posed by a student (Reddy et al., 2003). Hermann and Finn (2002) described the role of the school counselor in threat assessment as follows:

> According to current school violence and student suicide jurisprudence, school counselors are justified in taking every threat of violence or suicide seriously. Yet, some courts have recognized that not all threats are serious threats to do harm. School counselors play a vital role in assessing these threats and working with administrators as they determine whether to remove a student from school because of a violent threat. According to legal dictates, threat assessment includes determining whether the language and context of the threat indicate a serious intent to do harm. A school counselor's previous interactions with the student are relevant in this determination, especially if the counselor has noted volatile behavior or the student has indicated suicidal ideation. Finally, school counselors need to consider other corroborating evidence such as the student's history of violent behavior. (p. 99)

The approach to assessing risk to violence recommended by Hermann and Finn (2003) emphasizes assessing risk on a case-by-case basis as opposed to employing the practice of profiling. *Profiling* is an a priori practice in which violence proneness is determined by identifying students who may share certain characteristics with previously violent individuals. Bailey (2001) and Vossekuil, Reddy, Fein, Borum, and Modzeleski (2000) urged caution in utilizing this method because research has shown that there is no valid profile of a school violence perpetrator. It may be stigmatizing or even a violation of a student's constitutional rights to have placement decisions (e.g., suspension) made on the basis of a profile alone.

On the other hand, Hermann and Finn (2003) believed that it is appropriate to consider the risk factors related to violent behavior when a student's behavior calls for attention (Kashani, Jones, Bumby, & Thomas, 1999). In Hermann and Finn's contrast of risk-factor analysis with profiling, they asserted that risk factors "encompass a broad range of indicators as opposed to one rigid, stereotypical profile" (p. 101). Risk factors for violence have been identified through research on individuals who have already engaged in violent behavior. Vossekuil et al. (2000), for example, analyzed 37 school shootings and discovered that the shootings were neither impulsive nor random. Most perpetrators had planned the shooting, engaged in behaviors of concern (e.g., looking for a weapon or expressing suicidal or homicidal thoughts in a school assignment), and told at least one other person of their plans. Many of the perpetrators were also found to have been alienated from the mainstream of the student body, had been bullied or teased, and had recently suffered a relationship loss.

When a counselor does determine that a "true threat" exists, he or she, after considering all of the indications of risk, must act to minimize the threat. If the threat is to the school setting, the counselor's findings can be reported to the administration or school security personnel. In a *Tarasoff*-type of situation, where the threat is to an individual outside of the school (e.g., to a parent), the counselor may have an obligation to warn or take some other action to protect the intended victim if it is determined that a threat exists. Ethical codes permit disclosure in this situation, and some urge that the student be involved, if possible, in the decision to warn or protect the intended victim. The need for confidentiality may enter into the school violence situation in another important way, protecting the anonymity of students or others who report to the counselor that another student is planning a violent act. As Vossekuil et al. (2000) found, 75% of perpetrators of school violence had told at least one other person of

their plans. The receiver of this information may be more likely to tell someone who can help to avert a disaster if he or she does not fear retaliation or ostracism for "calling out" a peer.

Students at Risk for Suicide

Following a Maryland court case (*Eisel v. Board of Education,* 1991) in which school personnel were found liable for a student suicide, school counselors became more acutely aware of their responsibilities toward students at risk for suicide. In the *Eisel* case, school personnel failed to provide reasonable care to prevent the suicide. Other states have been reluctant to impose liability on schools for student suicides, and some commentators (e.g., Remley, Hermann, & Huey, 2003) suggest that courts may do so only when gross negligence is present. Nonetheless, the reasonableness standard of care and ethical principles place an obligation on school counselors to take action to prevent suicide (King, Price, Telljohann, & Wahl, 2000). Remley et al. identified the following as required under a reasonable care standard: "Taking every threat of suicide seriously, taking precautions to protect the child, and notifying the parents that the child is at risk for suicide" (p. 62).

Capuzzi (2002), in a very comprehensive article on preventing student suicide, after considering the legal and ethical mandates, advocated the "best practice" approach to suicide prevention. According to Capuzzi,

> Best practices are the aspirational standards an ethical and well-informed school counselor should seek to attain in the process of planning and implementing school-based prevention, crisis management, and postvention efforts. They can be distinguished from minimally acceptable practices which, though meeting most legal standards, may not provide maximum protection to students and their families. (p. 65)

The best practice approach, advocated by Capuzzi (2002), recommends that a comprehensive suicide prevention program be in place for all levels of schooling, including provisions for prevention, crisis responding, and postvention. At the prevention phase, Capuzzi recommended that (a) support for programs be obtained from all levels of administration; (b) all faculty and staff be educated about the characteristics of youth suicide, local and building policies and procedures for making referrals, and their roles in prevention; (c) crisis teams be developed and prepared; (d) access be provided to individual and group counseling for affected students; (e) parents be educated about the signs of suicide and any school protocols for dealing with students who are at risk; and (f) classroom presentations be offered to educate all students about suicide and how to access help for themselves and their friends. At the crisis management stage, Capuzzi acknowledged that the usual counseling skills that school counselors possess must be supplemented by crisis-oriented skills:

> The word *management* means that the professional involved must be prepared to apply skills that are different from those required for prevention or postvention counseling. An adolescent in crisis must be assessed, directed, monitored, and guided for the purpose of preventing an act of self-destruction. (p. 73)

Capuzzi (2002) suggested that the counselor be calm, supportive, and nonjudgmental and encourage self-disclosure. While the reality that suicide may be a choice may be acknowledged, it should not be *normalized* as a choice. He recommended that in-depth counseling not begin during the crisis stage and that assessment of the student and lethality be done with the collaboration of another professional. Among the management decisions that must be made at the crisis stage is taking measures to protect the student (e.g., not leaving the student alone or not sending the student home without being accompanied by a parent) if an assessment by at least two professionals determines the student to be at high risk. These measures include notifying parents, making a referral to an outside agency, and considering hospitalization. He further recommended that steps be taken that would not permit the student to return to school without clearance from a qualified professional.

Among a list of suggestions for the postvention phase, Capuzzi (2002) recommended a systemic response, including a meeting to provide consistent information to all faculty and staff. Although his best practice approach includes providing support for friends, classmates, and the deceased's family, he did not recommend that the victim be memorialized in school.

The school counselor should be reminded that confidentiality of counseling information is presumed to extend even into death. Therefore, the counselor should be vigilant about not disclosing information that may have been communicated within the confidential counseling relationship.

Military Recruitment of Students

Two acts of Congress in the early years of the 21st century, coupled with the war in Iraq, flamed historical controversy regarding the cooperation of schools in military recruitment. The current legal requirements for cooperation are contained in the Elementary and Secondary Education Act, as amended by the No Child Left Behind Act of 2001 (P.L. No. 107-110) and in the National Defense Act for Fiscal

Year 2002 (P.L. No. 107-107), the legislation that provided funding for the nation's armed forces in fiscal year 2002. Together these pieces of legislation require LEAs that receive any funds from ESEA to provide the same access to military recruiters as is extended to college recruiters and employers. This includes, for example, space at a career fair and disclosing directory information, including students' names, addresses, and telephone listings (USDE, 2002).

FERPA was also amended to exclude the requirement for parental consent to provide directory information to military recruiters. However, under FERPA, LEAs must notify parents that directory information will be disclosed to the military unless the parents take action to opt out (i.e., to notify the LEA that directory information must not be released to the military without their consent). LEAs may not make any policies that would prevent them from releasing the information to the military, other than in accordance with procedures for opting out.

Critics of the opt out policy are concerned that it places an affirmative duty on the parents to request to opt out as opposed to a policy respecting confidentiality that would require parental action if they wish to have directory information released. Although it is primarily an administrative responsibility to inform parents of the opportunity to opt out, the school counselor may want to be involved on the development of opt out procedures and provide oversight on the accuracy and accessibility of the documents that carry the required notices to parents and students.

Negligent Advising

School counselors were put on notice in 2001 that course advising is a function that may be scrutinized by courts. The occasion was a lawsuit brought by Bruce Sain, a senior at Jefferson High School in Cedar Rapids, Iowa, because he had been denied the opportunity to play basketball as a college freshman (*Sain v. Cedar Rapids Community School District,* 2001). The NCAA had found him ineligible to compete because he had not completed the required core English credits in high school. Coming into his senior year, he lacked three credits of English. He intended to take one course each trimester of his senior year to fulfill the requirement. He completed one course during the first trimester. After enrolling in an NCAA-approved course during the second trimester, Sain asked his counselor if he could transfer to a different English class. The counselor recommended a course entitled *Technical Communications*, which the counselor said would be consistent with his interest in computers and would count toward the NCAA core English requirement. He completed this course and another during the third trimester. However, shortly after graduation he was informed that he would be ineligible to play as a freshman and that he would lose his scholarship. The NCAA had determined that the Technical Communications course had not been approved because it had not appeared on a list of courses that the school had submitted for approval.

The trial court dismissed Sain's claim because it appeared to be a claim for educational malpractice, which, for a number of reasons, could not be brought in Iowa (or for that matter, in most other states). Sain appealed to the Iowa Supreme Court. There, the case took a very unexpected turn. The Iowa Supreme Court distinguished the claim of inappropriate advising from those usually falling under the educational malpractice rubric and, instead, advanced a novel theory under which Sain's claim would be able to go to trial. Instead of categorizing it as a claim alleging educational malpractice, the court found that it fit the requirements for the tort of *negligent representation.* Negligent representation is more commonly found in the business setting in cases against attorneys and accountants, in which a client relies to his or her detriment on information that proves to be inaccurate. Casting the case in this framework, the court ruled that the case should be allowed to go to trial.

The courts held,

> The tort of negligent misrepresentation is broad enough to include a duty for a high school guidance counselor to use reasonable care in providing specific information to a student when the guidance counselor has knowledge of the specific need for the information and provides the information to the student in the course of a counselor-student relationship, and a student reasonably relies upon the information under circumstances in which the counselor knows or should know that the student is relying upon the information. (*Sain v. Cedar Rapids Community School District,* 2001)

The decision has been both applauded (Willis, 2004) and derided (Abbott, 2002). What implications does it have for school counselors?

There are at least three provisions in the ASCA (2004) ethical code that have some bearing on the issue of providing accurate information to students:

> A.1.d. Is knowledgeable of laws, regulations, and policies relating to students and strives to protect and inform students regarding their rights.
>
> C.2.b. Provides professional personnel with accurate, objective, concise and meaningful data necessary to adequately evaluate, counsel and assist the student.

> E.1.b. Monitors personal well-being and effectiveness and does not participate in any activity that may lead to inadequate professional services or harm to a student.

It can be inferred from these provisions that counselors have an ethical obligation to provide accurate information to students. Do counselors now have a legal duty as well (Stone, 2002)? State courts in prior similar situations have found that school counselors do have a duty to act reasonably in all aspects of their work, including academic advising. If they have not been found to be individually liable for negligent advising in the past, it may have been because it has been considered to be a variant of educational malpractice, which is a tort that has been foreclosed by most state courts (Henry, 2004); it may also be the case that many states have statutes which provide immunity to public employees for negligent acts. However, if other courts were to follow Iowa's lead and distinguish negligent advising from other instances of educational malpractice, statutory immunity may be all that stands between the counselor and liability. Under the negligent representation theory, the school district could still be found liable even if individual employees are given immunity.

The Iowa Supreme Court was quick to refute assertions that permitting the *Sain* case to go forward would discourage counselor/student interactions and limit the flow of important educational and career information. The court assured critics that their ruling would pertain to only individual, face-to-face interactions and concerning only the accuracy of information. The tort of negligent representation does not cover opinions or projections, only the accuracy of the information on which those opinions might be based. In addition, counselors should be reminded that *Sain* is precedent only in the state of Iowa. School counselors should seek consultation regarding their own state's laws on the applicability of the tort of negligent representation to information communicated during academic advising. They should also seek advice as to whether their state statutorily provides immunity to school counselors.

Following the *Sain* decision, Stone (2002) made several recommendations to school counselors that might lower their risk for liability in their roles as academic advisors:

> Continue to offer academic advising sessions to students. The *Sain* ruling should not deter the active pursuit of the role of career and academic advising, a role that has the greatest opportunity for implementing a social justice agenda to level the playing field for students. . . .
>
> Act as the reasonably competent professional would. If faced with a lawsuit, school counselors who practice with care and caution will pass the standard of care test. The courts are not asking for extraordinary care, only reasonable care. . . .
>
> Stay abreast of the information needed for competent academic advising. It is important to be able to demonstrate a working knowledge of procedures, policies, laws, ethical standards, and the school district's policies. . . .
>
> Empower others to take responsibility for having and giving the right information. For example, coaches could be in charge of advising students about NCAA regulations, and students could be encouraged to learn to become their own advocate in gathering information about college admissions, scholarships, and financial aid. . . .
>
> Require that students and parents sign off when they have been given critical information. For example, when seniors are given their personal credit check for their remaining graduation requirements, the school counselor can have them sign an acknowledgment that they have been told and understand what they need to do.
>
> Consult when appropriate. Best practice for school counselors is to always consult whenever they are unsure. School counselors never stand alone unless they fail to consult with others who are in a position to help.

Recommendations for School Counselors

We will take one more opportunity to remind the reader that this chapter makes no representation to be comprehensive in its coverage. It is best characterized as a primer on law and ethics in school counseling. Where might one go to increase ethical competence?

1. Among the major topical omissions in this chapter are dual/multiple relationships, testing and assessment, and responsibilities of the counselor as a practicum or internship supervisor. The reader is urged to obtain in-depth information on these topics. Most entry-level textbooks on ethics in counseling will cover these topics (e.g., see Corey, Corey, & Callahan, 2003; Welfel, 2002).
2. School counselors could also benefit immensely from graduate courses or in-depth continuing education on school law and the law of special education taught by experts in these fields.
3. Counselors are always urged to seek consultation from their peers and superiors when entering unfamiliar territory.

4. School counselors should become thoroughly familiar with the relevant policies of their local educational authority. In addition, they should avail themselves of relevant resources and services provided by their state departments of education.
5. In order to accommodate the cultural diversity of their clientele, school counselors should proactively include parents and community members in formulating counseling and guidance policies and encourage administrators to do the same.
6. Preservice school counselors are urged to expect substantial training in law and ethics in their graduate programs. This training should include not only an introduction to professional ethics codes, but also the relevant laws in the state in which the counselor will be licensed.
7. Preservice counselors should expect that their graduate preparation include attention to developing multicultural awareness and skills at a level that is congruent with the ethical principle of competence.
8. School counselors should demand access to competent legal advice by attorneys who are knowledgeable about the issues relevant to the roles and functions of school counselors.

Summary

We hope that the reader has acquired a broader and more complete understanding of the full array of entities whose laws, policies, and principles shape their daily work. It should be apparent, however, that legal and ethical issues are complicated and unique to each individual situation. Because of this complexity, this chapter should not serve as a substitute for school counselors' getting their own competent legal advice when faced with a conflictual situation. It is our expectation, however, that the school counselor will now be in a better position to know some of the critical questions to ask when consultation is sought.

XLVII
PROFESSIONAL ACTIVITIES IN PROFESSIONAL SCHOOL COUNSELING

KEITH M. DAVIS, LAURIE L. WILLIAMSON, AND BARBARA A. SCARBORO
Appalachian State University

Introduction

This chapter discusses issues in professional school counseling regarding the professional activities and development of professional school counselors. Specifically discussed are (a) a brief history of the counseling profession; (b) credentialing, licensure, and accreditation in professional school counseling; (c) networking and collaboration; (d) partnering with local school systems; (e) technology; (f) differences in professional activities for school counselors based on geographical regions (rural, suburban, and urban) and grade levels (elementary, middle, and high school); (g) national, regional, and state school counseling organizations; and (h) the importance of advocacy as an underlying component for professional activities.

As professional school counselors move from their formal training to practice, it is important that they actively seek ways to maintain professional competence by keeping abreast of current changes in the school counseling profession. In doing so, they not only help promote the profession of school counseling, but also enhance their own senses of professional identity and advocacy for the constituents they serve (e.g., students, faculty, community, and society). To provide guidance for this professional development task we propose, in this chapter, a variety of ways in which professional school counselors can utilize professional activities and opportunities to maintain their professional identities, serve as advocates, and stay connected with each other as the school counseling profession continues to evolve.

Brief History of Professional School Counseling

Guidance and counseling as a profession was a latecomer to the field of education as the 1940s and 1950s witnessed a rapid expansion in the number of school counselors. School counseling was originally founded in the vocational movement that offered occupational assessment information and employment services. Thus, schools were encouraged to assist students in planning for their employment futures. Teaching and administration and their respective roles and responsibilities were already well established. Historically, teaching certification and experience has been a prerequisite for obtaining school counseling licensure in some states. Initially, school counselors were selected from within the ranks of the teaching staff. The standard expectation for school counselors was 1 to 2 years of teaching experience. The expectation that counselors were teachers first became established early in credentialing requirements. The struggle to define school counseling as a distinct profession continues today (Baker, 1994; Williamson, 1998).

It was the space race following the launch of Sputnik I, however, that really ignited the expansion of guidance and counseling services in the schools during the 1950s and 1960s. The National Defense Education *Act* (NDEA) of 1958 provided schools with financial support to hire counselors. The Congressional directive was to identify talented students and encourage them to pursue advanced study in math and science so that the United States would become more competitive with the then Soviet Union. The American Personnel and Guidance Association (APGA), which

eventually became the American Counseling Association (ACA), and the American School Counselor Association (ASCA), which was established in 1952, worked together to increase interest in counselor training, preparation, and licensure (Lambie & Williamson, 2004).

In 1969, the vast majority of states required teaching experience for counseling licensure but the trend providing for substitute or comparable experience was becoming more evident. Robert Myrick (1993) reported that 21 states required teaching certification and/or one or more years of teaching experience. Changing professional identification from one role to another (teacher to counselor) requires a substantial paradigm shift that is often difficult to achieve (Baker, 1994; Baker & Herr, 1976; Cohen, 1961; Smith, 1994). This has led to an increasing number of states allowing certification as a school counselor for individuals who have completed master's level training but do not hold a teacher's certificate.

The need for schools to employ clinically capable school counselors is evidenced by the increase and severity of issues facing schools today. The National Education Commission on Time and Learning (1994) reported,

> Half of American children spend some portion of their childhood in a single-parent home; 20.8 million working mothers have children under the age of 17; family time has declined 40% since World War II; 40% of high school students care for themselves after school; and . . . students are bringing many more problems to school . . . receive less support outside school, and increasingly exhibit destructive behavior ranging from drug and alcohol abuse to gang membership and precocious sexual activity. (p. 3)

In addition, schools are experiencing varied enrollment trends. The number of school districts and schools has declined from 1937 to 1938, when the first numbers were documented, to the year 2000. Reportedly, 117,108 school districts encompassing 250,000 schools have decreased to 14,928 school districts and 92,012 schools. These statistics and contributing factors are chronicled on a dedicated Web site of the Rural School and Community Trust (n.d.; http://www.ruraledu.org) providing detailed information regarding the status of rural communities and education. After multiple incidences of consolidation, rural school closings created situations where students endure long round trip bus rides to schools, as well as getting up early to arrive at school on time. Rural information highlighted the advantages of smaller schools and districts promoting higher student achievement, even among economically challenged students. Other advantages included that these rural areas are more productive in social and economic domains. In contrast, urban schools districts are growing with additional pressure to ensure equity in education and resources across the districts. The focus of concern shifts to the resources that schools and students have, instead of what students learn. Small rural schools that are a part of an urban district tend to experience greater challenges in the areas of equitable resources and education. Despite the challenges, many rural areas are embracing their communities and are developing policies and procedures (i.e., additional funding, financial incentives) to support educational efforts. Recent immigration trends put additional pressure on schools in many areas, urban and rural, to address the unique needs of bilingual and bicultural children (Towner-Larsen, Granaello, & Sears, 2000).

The ASCA rose to the challenge of redefining the school counselor's role by developing the *ASCA National Standards for School Counseling Programs* (Campbell & Dahir, 1997). The *National Model* (ASCA, 2003) addresses the needs for a comprehensive and developmental approach to the delivery of services. The *National Model* values systemic activities that impact all students at all levels. School counselors are encouraged to consult and collaborate with a wide variety of educational and community resources. The ASCA model also provides school counselors with accountability strategies to demonstrate program effectiveness (Lambie & Williamson, 2004).

Professional organizations such as the ACA, the ASCA, and the Association for Counselor Education and Supervision (ACES) are calling for uniformity in counselor education and training and in licensure standards. National Board for Certified Counselors (NBCC) has developed criteria for a Nationally Certified School Counselor (NCSC). The National Board for Professional Teaching Standards (NBPTS) has developed criteria for National Board Certification. It is hoped that by achieving a level of national conformity, levels of consistency will be established and the availability of state reciprocity policies will be increased. As a result, school counseling will be empowered as a profession.

Credentialing, Licensure, and Accreditation in Professional School Counseling

What exactly do all of those confusing acronyms mean? There are accrediting boards to evaluate educational training programs as well as certification and licensure boards for individual professionals. School counseling training programs are monitored by two main organizations: the Council for Accreditation of Counseling and Related Educational Programs (CACREP) and the National Council for

the Accreditation of Teacher Education (NCATE). These accreditation bodies develop and monitor the training standards of some professional school counseling programs (Figure 47.1).

Certification and Licensure

First, school counselors need to be licensed by the state Department of Education. But, they also have the opportunity to extend their professional development by meeting the criteria for national recognition. The NBCC was established in 1982 to support the standardization of the counseling profession by creating and monitoring a national certification system. The NBCC evaluates the professional training and competence of counselors from a wide variety of specialties by administering the National Counselor Examination (NCE) for licensure and certification. The NCE is designed to be general in nature and is intended to assess cognitive knowledge, regardless of individual areas of specialization. The NCE covers eight core areas: (a) human growth and development, (b) social and cultural foundations, (c) helping relationships (including counseling theories), (d) group work, (e) career and lifestyle development, (f) assessment and appraisal, (g) research and program evaluation, and (h) professional orientation. The examination is administered nationwide semiannually in April and October. Prerequisites for taking the examination include (a) a master's degree, (b) documented 2 years professional counseling experience, (c) 3,000 client contact hours, and (d) 100 hours of supervision (NBCC, n.d.).

Graduating from a CACREP program affords you the opportunity to waive the previously mentioned requirements and sit for the GSA-NCE (Graduate Student Administration-National Counselor Examination) at the end of your program. Satisfactory performance on the NCE is one of the criteria used by NBCC to identify professionals who may be eligible to become a National Certified Counselor (NCC). Being an NCC attests to your status as a professional counselor and advocate for the profession, and it is nationally recognized. You can also apply to receive specialty certification in the areas of (a) career, (b) gerontological, (c) school, (d) clinical mental health, and (e) addictions counseling. Certification is for a period of 5 years. At the conclusion of each 5-year cycle, you are required to document 100 contact clock hours of continuing education credit (NBCC, n.d.). Study guides for the NCE are available from the NBCC. (The contact information is National Board for Certified Counselors, Inc., 3 Terrace Way, Suite D, Greensboro, NC 27403-3660; phone 336-547-0607; fax 336-547-0017; e-mail nbcc@nbcc.org; and Web site http://www.nbcc.org)

After you have received initial certification as a counselor, many states offer licensure. Later in your career, you may choose to pursue your license and become a Licensed Professional Counselor (LPC). This designation affords you the opportunity to conduct private practice and receive third party payment from some insurance companies. LPCs are licensed by each individual state, and regulations vary from state to state. Generally, it is required that you (a) graduate with a master's degree from an accredited institution; (b) document 2 years of professional experience, 2,000 hours of supervised professional practice, 100 hours of clinical supervision (75 hours must be individual supervision and supervisors must be LPCs or equivalently credentialed mental health professionals with at least 5 years of counseling experience); (c) successfully pass the NCE; and (d) submit an acceptable Professional Disclosure Statement. Licensure is valid for 2 years, and you must earn 40 hours of continuing professional education credit during each 2-year renewal period.

School Counseling Licensure

In most states, a specialty area test is required by the state Department of Education in order to become a licensed school counselor. Many states use the Praxis (n.d.) series published by the Educational Testing Service (ETS) to evaluate mastery of basic counseling skills. School counselors frequently need to take the school counseling specialty portion of the Praxis to become licensed in that state as a school counselor. Qualifying scores vary from state to state (Praxis). Many states also require that all licensed school personnel pass a computer competency exam. Some states have included testing components that require the satisfactory demonstration of the use of word processing, database, spreadsheet, and Internet computer competencies. In 2005, the U.S. Department of Education, recognizing the increasing importance of technology, established action guidelines for the nation's school districts in preparing students for innovative approaches to learning through advances in educational technology. (The full text of the National Education Technology Plan is available at http://www.ed.gov/technology/plan.) It is a good idea to demonstrate the application of these competencies by developing a technology portfolio over the course of your career. A technology portfolio contains evidence of your technological skills, such as developing a parent brochure, an information Web page, or a PowerPoint presentation for staff development.

Every state has its own requirements; being licensed in one state does not necessarily translate into automatic licensure in another. A publication with information regarding state requirements for school counseling licensure and reciprocity with other states is available through the ASCA office. Professional organizations for school counselors include the ASCA (801 North Fairfax Street, Suite

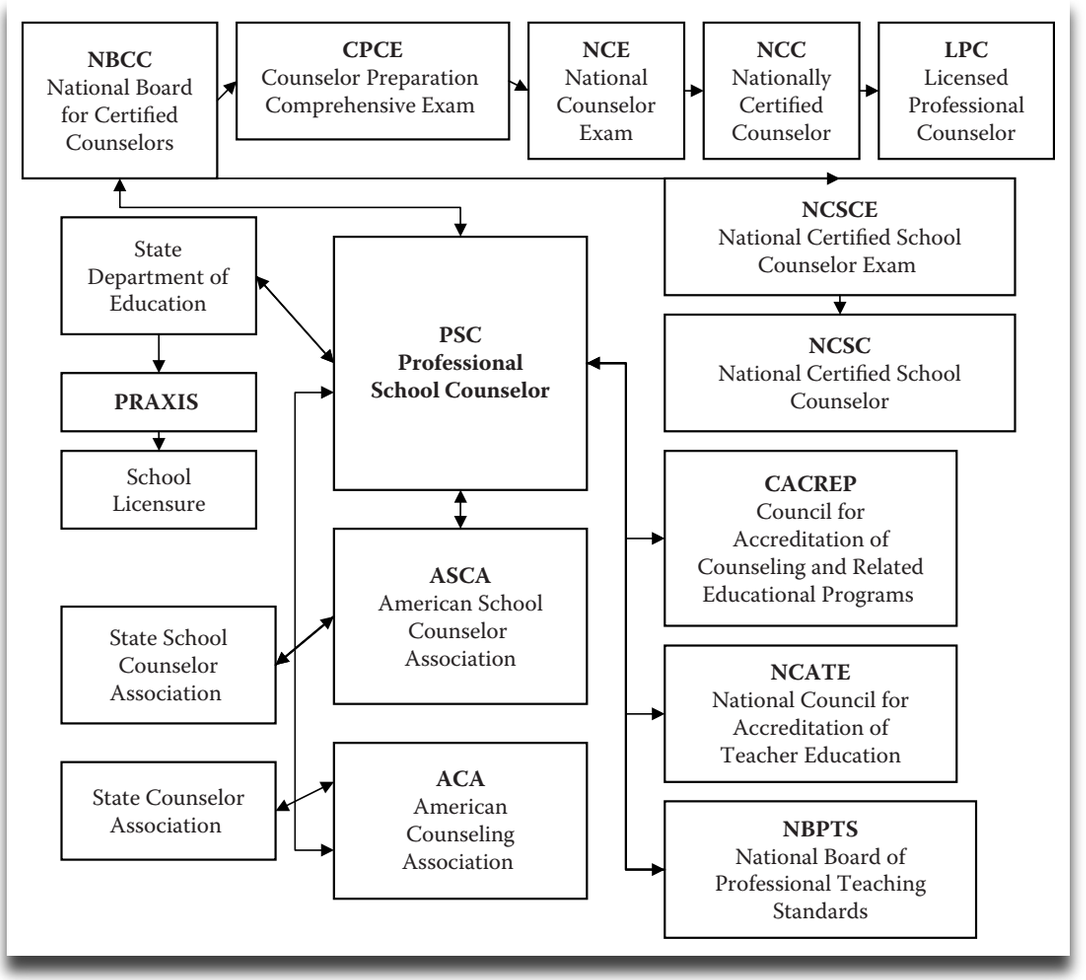

Figure 47.1 Professional Organizations and Credentials for School Counselors.

310, Alexandria, VA 22314; phone 703-683-2722 or 1-800-306-4722; fax 703-683-1619; e-mail asca@schoolcounselor.org; and Web site http://www.schoolcounselor.org) and the ACA (5999 Stevenson Avenue, Alexandria, VA 22304; phone 1-800-347-6647 ext. 222; fax 703-823-0252; and Web site www.counseling.org).

Advanced School Counseling Certification

The NCSC credential is a result of the joint efforts of the ACA, the ASCA, and the NBCC. Requirements include (a) a current NCC credential; (b) an advanced degree in a mental health field from an accredited institution; (c) coursework in appraisal of individuals, diversity in counseling, career development, and fundamentals of school counseling; (d) 3 years of postgraduate counseling experience and counseling supervision as a school counselor; and (e) a passing score on the National Certified School Counselor Exam (NCSCE). The NCSC is an attempt to standardize the school counseling certification process nationwide and provides criteria for school districts to provide school counselors with additional salary compensation (NBCC, n.d.). (The contact information is National Board for Certified Counselors, 3 Terrace Way, Suite D, Greensboro, NC 27403-3660; phone 336-547-0607; fax 336-547-0017; e-mail nbcc@nbcc.org; and Web site www.nbcc.org.)

Additionally, the NBPTS developed a board certification process for school counselors in 2002. The "Early Childhood Through Young Adulthood/School Counseling" certificate is appropriate for counselors who work with students ages pre-K–12th grade in educational settings. Requirements include a portfolio that demonstrates that your counseling practice meets the school counseling standards and that you monitor and refine your practice through continuous and in-depth reflection. Certification also requires an assessment process where counselors demonstrate content knowledge in the areas of (a) human growth and development, (b) school counseling program standards, (c) diverse populations, (d) theories, (e) data and change, and (f) collaboration (NBPTS, n.d.). Currently many states are providing additional salary compensation for school counselors who have successfully completed the board certification process. (The contact information is National Board for

Professional Teaching Standards National Office, 1525 Wilson Blvd., Suite 500, Arlington, VA 22209; phone 703-465-2700 or 1-800-228-3224; fax 703-465-2715; and Web site www.nbpts.org.)

Although all of the acronyms may be confusing, these organizations are important because they provide professional development opportunities, advocate for political and social support, and provide research-based resources. Membership in professional organizations is critical in promoting and advocating school counseling as a profession.

Networking and Collaborating

The DeWitt Wallace-Reader's Digest Fund contributed millions of dollars to jump-start an initiative to transform school counseling nationwide (Guerra, 1998). The multiyear initiative is called the *National Program for the Transformation of School Counseling* (NPTSC; Education Trust, 1999). The goal of the program is to improve the school counseling profession by transforming the preparation of counselors. Specifically, a large component of this preparation model includes training school counselors on how to meet the academic, career, and personal/social needs of underrepresented groups through social justice advocacy. This effort is aimed at closing the achievement gap of low-income students and students of color from other youth by promoting collaborative partnerships between local education (e.g., school counselors) and business, community activists, colleges, and whole communities so that all students will reach high levels of academic achievement.

Pedagogical trends encourage collaborative learning techniques (Gibson & Mitchell, 1992). Educators highlight the need for collaborative partnerships. Partnerships are forged between local schools, institutions of higher learning, and community leaders in business and industry in order to better prepare students for the modern work environment (Kurpius & Rozecki, 1992). One of the major problems identified by Guerra (1998) is that school counselors are trained in isolation from teachers, administrators, other school personnel, and the community, all of whom must collaborate to support and advocate success for all students.

Student counselors are trained in isolation from the other school professionals with whom they will be working on a daily basis. The NPTSC suggests that institutions of higher education must adapt their training programs in order to better integrate the training of school counselors with teachers. If collaborative teamwork in the schools is the ultimate goal, then it must be an integral part of the training process for teachers, counselors, and administrators.

There is minimal research available on promoting collaborative training programs. Only a few progressive programs provide opportunities for students to learn and collaborate across disciplines during their training. Shoffner and Williamson (2000) described an "innovative seminar" component of their training program in which counseling and administration students develop cooperative and collaborative strategies for working together in the school setting. Shoffner and Briggs (2001) created an interactive CD-ROM to challenge school counselors, teachers, and administrators to solve problems collaboratively.

Beesley (2004) suggested university training programs prepare students to facilitate "no-fault problem solving meetings" with teachers, students, and parents as active participants. This method was borrowed from the Ackerman Family Institute, which developed the model to stimulate cooperative planning and problem solving. Beesley also recommended that university programs develop advisory boards comprising school counselors, administrators, teachers, and members of the community to provide input and feedback on current issues, trends, and needs. Training programs need to develop curricula that focus on collaborative approaches to problem solving and provide students opportunities to practice collaborative or no-fault techniques. Finding ways to integrate the training of school counselors with that of other school professionals, particularly administrators and other pupil services personnel, is a vital need for the future.

The Counselor's Perspective

The No Child Left Behind Act (NCLB; U.S. Department of Education, 2001) is a federal mandate for public schools to effectively teach and ensure academic success for all students regardless of their race or socioeconomic status. In order for school counselors to better serve as advocates for all students, it becomes important for them to educate others within the school about their role and responsibilities. One of which is to promote social justice and to advocate for closing the achievement gap between minority and white students. Unfortunately, one of the most significant stressors identified by professional school counselors in the field is the lack of a clearly defined role (Kendrick, Chandler, & Hatcher, 1994; Studer & Allton, 1996). NCLB and the Education Trust (1999) initiative are among the developmental changes in the professions that have created changes in the roles and functions of school counselors within the schools. Thompson (2002) defined the changes as two dichotomous functions identified as administrative and therapeutic. Professional counselors indicate that the role of the school counselor is not well understood. Counselors' roles appear to have conflicting expectations from teachers, administration, and the counselors. Teachers perceive counselors as a part of the administration, administrators feel counselors are a part of the instructional staff,

and counselors report a sense of "inbetween-ness" (Snyder & Daly, 1993; Welch & McCarroll, 1993). Both perceptions are complementary of the administrative role identified by Thompson. Part of the reason counselors may feel isolated or caught in the middle is due to a tradition established in many schools. The tradition fosters the belief that the teacher is ultimately responsible for the students' learning. Administrators, parents, or counselors are consulted with only when a problem arises. Job descriptions are most commonly carried out in isolation. Efforts to strengthen communication and relationships between all stakeholders need to become more vigorous.

One major study conducted by Amatea, Daniels, Bringman, and Vandiver (2004) implemented a 3-year, school-wide intervention strategy to promote a more collaborative work environment among counselors, teachers and parents in order to enhance student learning and achievement. Their success in creating organizational change is encouraging to those who want to promote a collaborative partnership model. Amatea et al. found that there must be authentic dialogue and cooperation between school and home for effective problem solving to occur. One key component to their program was a "no-fault" approach to problem solving. Another key factor appeared to be more actively involving students themselves by promoting student-led parent conferences and portfolio assessments. Their project is described clearly, and it could be feasibly duplicated as one way to advocate for student success and achievement. Of interest to those schools that want to implement such a program is a study conducted by Marlow, Bloss, and Bloss (2000). Recognizing that there are multiple learning modalities, they focused on social and Emotional Competency Education (ECE). ECE encourages collaboration between teachers and school counselors and promotes the premise that emotional, cognitive, and behavioral skills are the foundations for academic success. Essentially, you cannot teach a student who is unready to learn. Marlow et al. also identified attitudes and barriers to the collaboration movement such as time constraints, lack of clear guidelines, and confusion regarding role definitions, job descriptions, and evaluations. Similarly, Davis and Garrett (1998) described concrete ways that school counselors can educate and collaborate with teachers on their roles as student advocates. Specifically, they described the importance of the consulting and collaborative roles of school counselors as a way of enlisting teachers in a cofacilitation process for meeting the developmental needs of students. Ponec and Brock (2000) stressed the importance of teamwork among the professionals at school. Collaborating for student success is critical if we want to improve school counseling services and increase student advocacy and achievement.

Teachers-in-Training Questions

Unfortunately, most teachers and administrators do not seek and are not required to take course work in school counseling (Gibson & Mitchell, 1995). Prospective teachers and principals can graduate from their education training programs with no exposure to school counseling programs or to how school counselors serve in the role of advocate for students and student achievement. Many classroom teachers feel uncertain about the goals of the school counseling program in their schools and lack communication and involvement in the counseling program. The results of Gibson's (1990) study, in which teachers' opinions about school counseling programs were elicited, indicated that teachers generally felt uninformed about the school counselors' functions. The biggest concern highlighted in this study was the pervasive failure of school counselors to adequately communicate their roles and responsibilities, especially when it came to advocating for student achievement and success. Additional training in the areas of effective implementation of comprehensive school counseling programs and appropriate networking and integration of the school counseling program should be sought by new professionals. The success of the program and the effectiveness of the school counselor are directly impacted by the perceptions of administrators, teachers, and staff. Professional development is an ongoing, lifelong process for school counselors to stay of abreast of current trends and best practices for effective programming.

Teachers' Roles and School Counseling

Teacher support and participation are crucial to any program that involves students. The school counseling program is no exception. The teacher, more than any other professional in the school community, is in the best position to know the students. Teachers communicate with students on a daily basis and can establish relationships based on mutual trust and respect. Teacher support can be especially influential in determining how students view and use the services of a schools' counseling program. Teachers are a major source of student referrals, and counseling programs must therefore depend on alert faculty to ensure that students with counseling needs will not go unnoticed or unreferred. Teachers should orient and encourage students to seek and follow through with counselor assistance (Gibson & Mitchell, 1995). Professional school counselors are encouraged to meet with faculty and staff routinely to keep channels of communication open regarding the needs within the school and the counseling services available (Sink, 2005).

Areas of Potential Conflict

Teachers and counselors, however, do have different roles and job descriptions. That being the case, it is natural that

conflict may develop between them. Researchers (Benshoff, Poidevant, & Cashwell, 1994; Cole, 1991; Idol & Baran, 1992; Kaplan, 1995; Studer & Allton, 1996; West & Cannon, 1988) have identified areas as having potential for conflict between teachers and counselors as (a) educational goals, (b) resources, (c) consultation efforts, (d) confidentiality, and (e) discipline.

Educational goals. Goals for educational and personal success are often perceived by teachers and counselors as being mutually exclusive. A teacher may not understand how personal counseling may benefit a student's academic learning. On the other hand, the counselor may view particular instructional practices in the classroom as detrimental to the student. An example might be that a student feels anxious about reading aloud in the classroom. The teacher is adamant that the student must complete the assignment and develop public speaking skills. The student feels trapped and comes to the counselor suffering from an anxiety attack. The student asks for the counselor's support. The counselor consults with the teacher and asks the teacher to consider some alternatives, such as allowing the student to tape record the readings or reducing the size of the audience. One hopes that the teacher, counselor, and student can agree to work together slowly and deliberately to build the student's confidence and ability to read aloud in class. Professional school counselors need to attend educational venues regularly to maintain professional skills and develop new areas of expertise. Conferences, in-services, and course work are all great ways to improve and expand one's repertoire of interventions and techniques (Remley & Herlihy, 2005).

Resources. Teachers and counselors often compete for the same limited resources, including time. Although time with students is the main conflict, competition may also come in the form of vying for money, equipment, supplies, physical space, and support services. An example might be competing with other faculty for budget money. How big is your piece of the pie? The resource teacher requests a budget based on the number of identified kids, which is often equivalent to a regular classroom teacher's budget. In other words, they are both providing for some 25 children. The school counselor, on the other hand, needs to advocate for the program and its mission to serve the entire school population. School counselors need materials for classroom guidance lessons (often used by 2 to 4 classes or 50 to 100 children at each grade level); small group activities; resource books for students, parents, and faculty; and so forth.

Consultation efforts. The roles of teacher and counselor are quite different from one another, and yet, when either professional takes on the role of consultant, there is considerable overlap. Unless teachers and counselors communicate and collaborate, there can be confusing or mixed messages provided to students, parents, and other educational and community supports. For example, a teacher has a student who is falling behind in math. The teacher requests that the parents make the student spend more time on homework, taking away privileges if necessary, until all assignments are complete. The counselor, meanwhile, learns that the student's grandfather recently died and encourages the parents to spend more unconditional time with their child and not to force homework battles. Both teacher and counselor need to share information and strategies on how best to support the student's academic as well as personal needs.

Confidentiality. Confidentiality is an ethical cornerstone in the counseling relationship. Confidentiality limits the information that counselors can share with teachers, parents, and administrators. A counselor promises not to reveal a client's information to anyone without the client's permission unless (a) the counselor's professional opinion is that the client intends harm to him or herself or another; (b) the client is the possible victim of abuse; or (c) the counselor is using the counseling information in clinical supervision. Teachers may not understand that counselors must abide by certain legal and ethical obligations. Unfortunately, from a teacher's perspective, confidentiality in the school setting limits the information available for sharing and problem solving. The counselor may appear self-important and uncooperative to the teacher who, on the other hand, is asked to share all information openly. School counselors need to be clear about their ethical and legal obligations. You will earn the respect and trust of others by handling situations as if they involved you personally. When and how would you want someone to share information about you? Advise others that you will divulge relevant information as needed, and ask them to trust your professional judgment. Your reputation will reflect your integrity.

Discipline. Counselors look for causes of behavior and identify poor self-esteem, dysfunctional families, and other interpersonal or intrapsychic issues that can lead to offending behavior. Counselors see discipline as student self-management. Counselors promote self-responsibility, behavior control, and personal accountability for actions. Teachers, on the other hand, are more whole-group student advocates who work to provide a safe, orderly, and productive learning environment for all. Teachers tend to look at the effects of the behavior and of how it may impede learning for others. Parents want the school to impart fair and equitable discipline that is consistent with community

values. The best way to resolve tensions around discipline is to implement a schoolwide discipline program that is positive and proactive. Incentives and/or privileges range all the way from individual students, to teams, to grade levels, and to schoolwide achievements. A discipline committee consisting of students, parents, and faculty would monitor and refine the program as needed.

The best way to resolve discipline issues and many others is to conduct your school counseling program in a collaborative, consultation fashion. A collaborative relationship with teachers and administration is integral to implementing an effective school counseling program.

Collaborative Consultation

An effective school counseling program is based on mutual respect, trust, and communication between school professionals. Because the school counseling program is the responsibility of counselors, they must initiate communication and interaction with teachers and administrators; they must actively pursue teachers' and principals' involvement and assistance to prevent and avoid conflicts. One method used effectively in schools to promote communication among school personnel is called collaborative consultation. Collaborative consultation can occur among any group of teachers, counselors, and administrators. Each professional in the school setting can complement the role of the others to achieve effective interventions and maximum productivity. The intent of collaborative consultation is to generate creative solutions to problems that could not otherwise be generated independently. Collaborative consultation is a process characterized by shared decision making, mutuality, and reciprocity (Bryan, 2005; Davis, 2005; Erford, 2003; West & Cannon, 1988; West, Idol, & Cannon, 1989). Idol, Paolucci-Whitcom, and Nevin (1986) emphasized that diversity of expertise is a valuable resource. Joint approaches to problem solving produce better solutions. Examples of collaborative consultation include child study teams, student assistance programs, and advisory committees. The outcome of this team process will provide comprehensive and effective programs for all students.

School Counselor Education Programs and Local School Partnerships

In an effort to decrease the gap between professional school counselor training and professional school counselor practice, it becomes important for training programs to partner with local school systems in providing professional development opportunities for practicing school counselors. In our program, we accomplish this through providing in-service training to professional school counselors employed in local school systems, as well as making resources available to them through our school counseling library and resource center.

Once a year, our school counseling program faculty provides a 3-hour, in-service training at our university on a current topic germane to professional school counseling. School counselors from local school systems are invited to attend to learn about current issues and receive continuing education credits. School counseling students are required to attend, not only to learn about current information but, more important, to see the importance of how we promote and advocate the school counseling profession. Additionally, the school counseling program faculty is able to model how to organize and deliver a formal presentation to both students and professional school counselors alike. This modeling not only serves to encourage students and practicing school counselors to present themselves, either to their own school systems or at professional conferences, but also fulfills the ethical obligation within the ASCA (2004) for school counselors to contribute to "the development of the profession through sharing of skills, ideas, and expertise with colleagues" (F.2.b.).

Supervision for professional school counselors has been identified as a growing need. Unfortunately, many school counselors do not receive the type of counseling supervision they would like or need. In an effort to provide this growing service, we make available at our state conference a supervision session for those practicing school counselors who are interested in time-limited supervision. These supervision sessions are typically open forums for school counselors to discuss and share their own continued development as professional school counselors, as well as to discuss certain cases with which they are having difficulty. The wealth of school counselor experience in these sessions is the valuable opportunity to connect with one another and share ideas about what is or is not working in their comprehensive developmental guidance and counseling programs. It is also an opportunity to share with practicing school counselors the current trends in the school counseling profession as it relates to school counselor education and training, and is in keeping within the ethical standards of the ASCA (2004) "The professional school counselor . . . actively participates in local, state, and national associations fostering the development and improvement of school counseling" (F.2.a.).

Technology

The technological revolution has and will continue to have a tremendous impact on the school counseling profession and how the role can be performed from career and college counseling to parent involvement. Recognizing this, the ASCA has been diligent in incorporating aspects of technological use in their role and position statements, as well as ethical codes. As a result, more school counseling programs are requiring that their students demonstrate how they plan to incorporate technology within their comprehensive guidance and counseling programs, and state licensing and credentialing boards are requiring current professional school counselors to attend professional development training regarding use of technology.

The Web site for the ASCA contains excellent articles and links to articles regarding a variety of ways that currently practicing school counselors are incorporating technology within their comprehensive school counseling and guidance programs. For example, Stone (2004) described how a high school counselor advocates for closing the achievement gap through technology by using an online career choice module to help students decide which science and math courses to take to achieve their career goals. As a result, this high school counselor noted a 40% increase in African American students choosing higher level math and sciences courses over a 6-year period using the module. Other article links include the use of technology in career, assessment, appraisal, enrollment trends, data collection, and parental communication, as well as strategies for making access to technology an equitable process for all students.

Currently practicing school counselors are also finding that a link to their school counseling Web site from the school's primary Web site is an equally useful and efficient way to connect with parents and caregivers on a variety of topics (e.g., school counseling program mission, ongoing school counseling activities, potential groups for students, and testing information). Professional school counselors should not just know how to use (e.g., navigate) Web sites, but also how to build and maintain their own Web sites as a way to keep their constituents updated and informed on their comprehensive school counseling and guidance programs. Stone (2004) summed up other important aspects regarding the interface of technology and school counseling, stating,

> Technology plays a critical role in providing accurate, timely data from student information management systems. School counselors using this data increase their ability to be another set of eyes and ears for social justice and advocacy; monitoring patterns of course enrollment, student access and success in higher level academics; delivering career and academic advising; managing resources to extend the reach of the school counseling program. (2004, ¶ 2)

Professional Activities in Rural, Suburban, and Urban School Counseling

Professional school counselors work in rural, suburban, and urban school systems, but may not be familiar with the varying needs that each system may require. In changing economic times, school counselors working in rural areas face the erosion of the agricultural and manufacturing industry, while urban school counselors face a crumbling infrastructure, both resulting in poverty for their constituents and a lack of resources in their school systems. Suburban school counselors are no strangers to harder times and dwindling resources as well; however, it is evident through census information that these systems are not facing the same economic struggles as those of the more rural and urban systems (U.S. Census Bureau, 2000).

If the school counseling profession is to continue to advocate and meet the needs of its constituents, then it can do so only as a united profession, with unification coming through understanding the varying challenges and needs of professional school counselors representing all economic and geographical regions of the country. Within the context of how professional activities can help facilitate this understanding, it becomes more important for all school counselors to have mechanisms in place for communicating with one another in order to advocate for and promote the academic, vocational, and personal/social development of their students. Attending state school counseling conferences, sharing ideas and thoughts via school counseling listservs and professional interest networks (PINs), and gaining membership in professional school counseling organizations are all powerful ways to unite the school counseling profession as a voice for advocacy within political and social systems. One recent example of how such united advocacy has worked in the school counseling profession is the development of the Education Trust (2000) fund, an organization promoting and providing funding to school counseling training programs to help close the achievement gap for minority students. Another such example is the National Center for School Counseling Outcome Research (n.d.), which helps train school counselors in documenting how what they do works, so that school counselors can

advocate and demonstrate data to school systems for the valuable work that professional school counselors do.

Reiterating once again that school counselors are part of the technological revolution, the ability to stay connected with the school counseling profession is more available now than at any other point in the profession's history. Using our collaborating and coordinating skills, professional school counselors are able to unite and advocate like never before through technology.

Professional Activities in Elementary, Middle, and High School Counseling

Professional school counseling roots are within secondary education, but are now found at all levels of a child's education providing essential services to promote the academic, vocational, and personal social needs. Although professional school counselors at all levels promote these services within their counseling, consulting, coordination, and collaborative roles, clearly children and adolescents have varying developmental needs and tasks. Thus, professional school counselors working within elementary, middle, and high schools may focus their professional activities to reflect advocating these varying developmental needs.

Elementary school counseling typically focuses on promoting and developing children's social skills, self-concept, and problem-solving skills. This is often carried out through group counseling and/or classroom guidance activities. Middle school counseling generally helps to assist in the transition from childhood to preadolescence. Much of the focus in middle school counseling is devoted to helping understand physical and social changes, including sexuality and peer acceptance. Middle school children have the ability to think more abstractly and begin developing rationales for their decision-making processes. In high school counseling, more emphases are placed on the career development of adolescents, preparing them for life after compulsory education, whether it is higher education or work. Although the argument can be rightfully made that all of these aspects are important at all levels of school counseling, differing developmental needs of children and adolescents may influence the degree to which certain services are employed by school counselors within elementary, middle, and high schools, which may in turn influence the degree to which school counselors seek professional activities that are more germane to their individual practice.

Within most professional school counseling organizations, there are distinctions and suborganizations that reflect the differing developmental levels and interests in school counseling. These distinctions provide a forum for professional school counselors to discuss and share issues and ideas specific to their developmental interests, through either newsletters or online listservs and PINs. Equally, school counseling state and national conferences typically have presentations and poster sessions specific to elementary, middle, and high school counseling. Colleges and universities are also increasingly providing advanced training to school counselors through evening, online, and summer school courses and institutes that target specific developmental levels. For example, at our university, we typically offer a summer institute course in creative and expressive arts techniques for use with children and adolescents, being sure that we address how each technique can be used at varying developmental levels. This type of integration helps to educate school counselors on how certain techniques can be used across a wide variety of developmental levels, and in the process, school counselors at all levels begin to see the connections and importance of transitional and developmental needs of all children and adolescents. Practicing school counselors are encouraged to continue their education after their formal training in order to keep up with the latest trends in working with a variety of age levels, and attending local colleges, universities, and workshops helps in promoting this professional identity and advocating for the profession by keeping abreast of current trends and research.

Another avenue for school counselors working at all levels of urban, suburban, and rural schools to continue their professional development, competence, and training is participation in their national, regional, and state counseling organizations.

National, Regional, and State School Counseling Organizations

School counseling programs throughout the country are placing a larger emphasis on school-counselors-in-training becoming more involved in their national, regional, and state school counseling organizations. Research has demonstrated that when students become involved in their professional organizations during their training, they are more likely to continue being involved and participating once they enter the school counseling profession (Erford, 2003).

Other than simply being a member of a professional school counseling organization, students and practicing professional school counselors have opportunities to not only attend conferences, but to present as well. By presenting at local, state, and national conferences, professional school counselors are adhering to the ASCA (2004) ethical standards by contributing "to the development of the profession through the sharing of skills, ideas and expertise

with colleagues" (F.2.b.). Two typical methods of presenting at professional school counseling conferences are a formal short presentation and a poster presentation.

Professional and Poster Presentations

Several months before a conference, organizations will put out a call through either a Web site or mailing about upcoming professional conferences. There will be an option to submit a presentation proposal, for which potential presenters can choose between a formal lecture-style presentation and presenting information in poster session format. Either format requires a potential presenter to fill out a brief synopsis of the information to be presented, a title, and a shorter description of the informational session that will appear in the conference bulletin should it be accepted. Contact information is also required for all presenters. Potential presenters then submit their proposals to the organization for blind review, and they will be contacted by the organization on a decision. Typically, national conferences are larger and more competitive, while regional and state conferences stand a better chance of accepting a potential presentation proposal.

Formal lecture-style presentations are generally an hour, allowing time for questions. So, presenters should be prepared to deliver information in an organized and concise manner, realizing that not everything about a chosen topic can possibly be discussed in such a short time. Overhead projectors are generally provided by the conference location, while other technologies (e.g., PowerPoint, digital, video) for presenting are the presenter's responsibility. Presenters should always have handouts regarding the information they are presenting, and the number of handouts needed is hard to predict.

Presenting a poster session generally involves the presenters organizing information in bullet form on a three-winged poster board, with additional material available in handouts. Poster sessions at conferences are generally scheduled for 2 hours and all poster presenters organize their posters on tables so viewers can walk past and read the information. Poster presenters stand next to their posters, greet the viewers, and answer questions about their chosen topics. Usually, having a small supply of candy or trinkets on hand to pass out to viewers is gladly accepted.

Participation in professional organizations through attendance at national, regional, and state conferences not only keeps the school counselor abreast of current trends within the school counseling professional, but more important, brings counselors at all levels together from urban, suburban, and rural schools to share ideas, information, and resources. Through presentations and general mingling, school counselors can learn more about what may work in other schools, especially when it comes to advocating for the profession and how school counselors can be instrumental in advocating success for all students.

Activities in Advocacy

To conclude, we propose here the importance of advocacy in the school counseling role as an underlying component to promote the academic, career, and personal/social achievement of all students regarding the previously mentioned activities. In providing comprehensive and effective programs for all students, school counselors should continue their professional development in a way that incorporates advocacy activities as a focus. Advocacy, as identified by the *ASCA National Model* (ASCA, 2003) is a key leadership role for the school counselor. Generally defined and responsibilities not enumerated, the goal of advocacy is to promote academic, career, and personal/social success for all students. For example, current focus on academic achievement gaps among students based on ethnicity and socioeconomic status (Education Trust, 2000), school safety (Hernadez & Seem, 2004), and student empowerment for social justice are issues for school counselors to address. Social justice issues encompass, but are not limited to oppression, prejudice, racism, inequities in education policies, procedures, resources, and the socialization of students in schools and in communities. These issues illuminate the need for training and the importance of the school counselor's role as an advocate. Most counselor education programs have limited focus in advocacy and social justice issues and response training (Bemak & Chung, 2005; Trusty & Brown, 2005). Training school counselors in these areas would benefit the delivery of comprehensive programming. Additionally, the school counselor would assume a pervasive leadership role in identifying and addressing the unmet needs of students, parents, communities, and schools, thus, supporting and empowering students to learn, feel safe, and achieve with adequate resources and programs.

Advocacy competencies for school counselors have been operationalized and discussed in the context of school counselors' roles (Trusty & Brown, 2005). Advocacy for social justice and equity involves identifying unmet needs and taking action to alleviate the contributing factors that sustain injustices and inequities. The efforts to alleviate or minimize these factors bring about systemic change and place value on individual expression of those involved. To achieve this end, school counselors must be competent in three advocacy areas: (1) disposition, (2) knowledge, and (3) skills (Trusty & Brown). Disposition entails ethical practices and risk taking to join and empower students and parents to eliminate known situations that impede learning and equity. Knowledge of resolving conflict, media-

tion, resources, and models of advocacy and change are important in advocating for students and parents. Data supported problem identification and effective articulation to administration, boards, and community stakeholders with suggestions for resolution compose the knowledge component. The skill component includes the developmental counseling skills already incorporated in most counselor education training programs: problem identification, effective communication, collaboration, organization, and care of self to avoid burnout. School counselors must be aware of the perceptions of students, families, and systemic underpinnings to promote discussion and change. Presenting the information in an assertive, empathic, and professional manner to support systemic change while maintaining relationships and alliances is one of the challenges of advocacy. Stress management and reduction are important for self-care as advocacy activities can be challenging, demanding, and sometimes frustrating.

A key advocacy activity identified as a critical role for urban school counselors in particular is closing the achievement gaps between students of color and White students and between lower socioeconomic status and higher socioeconomic status students. Individual student needs, school resources, and access to needed services are sources of social injustices, inequities in schools, and the need for advocacy activities (Bemak & Chung, 2005). Some factors that perpetuate these issues include "negligence, low expectations, and job goals and outcomes adopted by school counselors and other school personnel" (p. 197) as important, but may not reflect the consensus of the students and parents. These issues include racism, sexism, violence, bullying, discrimination, and poverty. Confronting these issues as leaders for change, school counselors must assume the role of social advocate for systemic change. Lack of advocacy and social justice training was identified as the culprit for school counselors' perpetuating the injustices and inequities in schools.

Bemak and Chung (2005) proposed three ways to integrate advocacy training into counselor education existing curriculum. Social change, social reform, and school reform can be discussed in required courses and advocacy activity required during practicum and internship placements. This level of training is referred to as preservice training. After the school counselor is working in the field, in-service training reflective of social equity, leadership skills, and advocacy can be provided with emphasis on the academic success of all students including students with disabilities, students of color, and those from challenging socioeconomic situations. Furthermore, school counselor supervision can entail an advocacy focus. The supervisor being a professor or one with advocacy training and experience can support and provide productive feedback for school counselor advocacy activities.

It is essential for school counselors to focus on the academic, social, emotional, economic, political, and other environmental realities of students and families. A student's relationship to the school climate should be viewed from perspectives of personal and interpersonal (student to parent, school personnel, and community). These relationships set the climate of the school, establish acceptable behaviors, and establish policies and procedures for behavioral consequences and school safety.

As advocates, school counselors can design and implement a comprehensive school counseling program based on students', families', communities', and schools' assessed needs. Prevention and intervention programs for all students at each school level can be designed to address issues such as bullying, anger management/leadership skills, mediation, and violence prevention to reach all students. Groups and assemblies, instead of individual sessions, would maximize a school counselor's time and address the increasing number of students assigned to each school counselor (Hernandez & Seem, 2004). Counseling and guidance programs can be utilized in the classroom using evidence-based curriculum. Proactive and not reactive programs (e.g., character education and substance abuse prevention) can provide students with concrete information for good and productive decision making. The goals of these activities will establish or further promote feelings of safety, readiness to learn, and the opportunity of academic success for all students.

SUBJECT INDEX

A

ABCD model of development, 703
Ability grouping, *See* Tracking and placement issues
Absenteeism and truancy, 272–273, 356, 638–639
Abstinence, 245, 247, 250–251
Academic achievement, 10, 51, *See also* Racial/ethnic minority students; Student performance outcomes
  accountability, *See* Accountability
  acculturation and, 184–185
  aggressive behavior and, 696
  caring environments and, 53, 59, 80, 356, *See also* Schools as caring communities
  college preparatory curriculum vs., 50, 51
  community involvement and, 58, *See also* School–community collaboration
  community or bridge programs, 189–190
  counselor advocacy roles, *See* Advocacy roles of counselors
  discrimination and, 52
  economic implications for non-graduates, 269–270
  emotional development vs., 563
  gender and, 51–52
  health and, 195–197
  intellective competence and, 54, 58
  locus of responsibility, 65
  parental involvement and, *See* Parental involvement
  poverty and, 51, 269–270, 537, 773
  racial identity and, 179–181, 322
  respect and, 58–59
  school failure, 635–647, *See also* Achievement gap; School failure
  school quality and, 53
  self-efficacy and, 183
  social class and, 51, 55, 99, 149, 294, *See also* Achievement gap; Socioeconomic status
  student accomplishment and, 50, 51
  student achievement data
    ASCA National Model and, 43, 45
    data-driven programs, 45, 51, 60
  students of color and, *See* Achievement gap
  teacher expectations and, 149, 638, 639, 640, 700
  teacher quality and, 53, 58
  "what works" interventions, 58–59
Academic failure, *See* Achievement gap; School failure
Academic press, 84–85
Academic records access, 794, 796
Academic self-efficacy, *See* Self-efficacy
Academic tracking, *See* Tracking and placement issues
Acceleration, 538–540
Access to records, 794, 796
Accountability, 112, 651, 758, *See also* Student performance outcomes
  ASCA National Model, 40, 44–45, 50–51, 217, 758
  evaluating school programs, *See* Program evaluation
  locus of responsibility, 65–66
  national standards for counseling programs, 38
  No Child Left Behind, *See* No Child Left Behind
  research, *See* Research
  school failure and, 636–637
Accreditation and certification, 298, 299, 402, 812–813, *See also* Counselor education and training
  advanced certification, 814–815
  CACREP minimal standards, 15–16, *See also* Council of Accredited Counseling and Related Educational Programs
  state licensure, 813
  supervision and, 19, *See also* Supervision
  teacher certification and, 28
Acculturation, 68–71, 96–97, 184–185, *See also* Assimilation
  academic achievement and, 184–185, 565
  acculturative stress, 69–70, 96
  "acting white," 179, 536, 548

cultural deprivation model, 101
culture shock, 69–70, 96, 98, 185
definition, 97
discussing issues of, 131
generation status, 97
group interventions, 443–444
intergenerational stresses, 82–83, 100, 323
psychological effects, 100–101
Acculturative environment of schools, 79–81, 83–89, 106, *See also* Acculturative press
effective schools and programs, 89–90
Acculturative press, *See also* Acculturation
academic press, 84–85
effective schools and programs, 89–90
immigrant parents and, 87–89
native language use in schools, 84
peer relationships and, 86
school adults and, 86–87
Achievement gap, 50, 51, 141, 177–190, 195, 197, 269, 294, 321–322, 564, 635, 766–767, *See also* Academic achievement; Racial/ethnic minority students; School failure
acculturation and, 184–185, *See also* Acculturation
anti-intellectualism and, 199
